Section of the fifth-nerve branches or the superficial cervical nerves has a certain limited field. The inferior dental nerve may be sectioned as it enters the dental canal in the lower jaw. The lingual nerve may be sectioned in the floor of the mouth. In lesions that are not too extensive both sections may be done.

The superficial cervical nerves may be sectioned as they emerge at the posterior border of the sternomastoid muscle. In this region one finds together, and may sever, an anterior, a descending and two ascending branches (great auricular and lesser occipital). This operation is applicable when the anterior neck triangle is involved, but not in the case of the posterior one, and is seldom done.

motor weakness, which may be transient or of long duration

In the higher lumbar injections there is subjective relief, and there may or may not be slight decrease in sensation in the lower extremities. If present, this is as a rule of brief duration. In the lower lumbar injections a hypesthesia or anesthesia of the saddle back type is frequently produced. It is relatively short-lived. The duration of relief varies. It may be days, a few weeks or longer, but ordinarily is sufficient for many of the well-advanced cases of cancer. Repeated injections are sometimes necessary. The interval between them should not be less than a week. If bilateral injections are done, it is well to limit somewhat the amount used each time. There is also some danger in elevating the hips too much, as the alcohol may extend to a level lower than desired, or may concentrate too strongly on the lowest roots, with resultant sphincter disturbance.

The length of time the patient's position should be maintained varies somewhat with different operators. Thirty minutes in the original position is about enough. It is generally felt that alcohol when given in small amounts shows some selectivity for the pain fibers in the nerve roots. These fibers are considered smaller and nonmyelinated, and thus more susceptible to alcohol. Beyond a certain point, sphincteric action as well as other forms of sensation and even motion may be affected.

Alcohol may be used above the cauda equina, and in some hands has been carried to the lower cervical level, but in such instances the procedure is fraught with a much greater degree of danger, owing to the proximity of the spinal cord and of the phrenic centers. The puncture is especially difficult above the lumbar region, and is not recommended except in isolated instances and in experienced hands. Multiple dorsal punctures with the injection of smaller amounts in each space have occasionally been used.

Further Procedures

The remaining procedures to be mentioned will not be given in detail. These are Gasserian-ganglion injection, myelotomy and presacral-nerve section.

Gasserian-ganglion injection has a limited field of usefulness, and carries with it the definite danger of injury.

The operation of *myelotomy* was introduced by Leriche in 1928, and independently by Dr Tracy J. Putnam, of Boston, for relief of high bilateral neck or shoulder pain. It is offered where high bilateral anterolateral-column chordotomy is contraindicated because of the danger of damage to the phrenic centers in the midcervical

cord. The occasion for its use is infrequent. In this operation, a narrow midline laminectomy involving several vertebrae and extending from about the midcervical to the upper dorsal region is done. A typical exposure would be from the fourth cervical to the third dorsal segment. Originally a long, fine, straight needle was inserted between the posterior columns of the spinal cord at intervals of a few millimeters up and down the exposed area, and was moved so as to pass through the commissure. A specially devised myelotome is now used. The procedure may be carried to a segment or two beyond the limits of the laminectomy. The resultant loss of sensation is two or three segments less in extent than the exposed cord. There is a loss of sensation to pinprick, but little if any loss of tactile or position sense. There may be slight atrophy of the small muscles of the hands, but this should not impair usefulness. There is no change in reflexes. In this operation there is obviously some danger of injury to the posterior columns, the anterior-horn cells, and the anterior spinal artery, and still some chance of involving the phrenic-nerve centers. So far as I know, this operation has not been done enough times to enable one to take a definite stand, although it seems to have possibilities. It should be emphasized that the loss of sensation following the operation is limited or segmental in type, and does not involve the entire body below a certain level or include the lower extremities, as is the case in anterolateral chordotomy.

Presacral-nerve section is of value in a limited number of cases with disease largely confined to the cervix or uterus. It is obviously unsuited to cases in which there are widespread metastases. I have had no experience with this operation. It can easily be done by the gynecologist or general surgeon during the course of pelvic surgery.

SUMMARY AND CONCLUSIONS

General considerations in the treatment of pain in cancer have been discussed. The role of referred pain has been mentioned, and the nerve supply involved in head and neck pain has been briefly described. The measures employed in relief of such pain have been listed. The general application of principles underlying the therapy that is employed have been given, and specific measures for relief of pain and their regional application have been offered.

The intractable pain of cancer, unrelieved by local surgery, x-ray or radium treatment or sedation, can be treated directly in a variety of ways—there being some form of treatment for almost every type of lesion in any location—and with some degree of success. The exact percentage of

cervical chordotomy may, however, be done simultaneously with a fair degree of safety. Chordotomy may be employed to help pain as high as the shoulder, but for relief of pain above that level posterior-root section may be necessary, although it should not be done bilaterally. Clinically, with this there is subjective relief from pain. Objectively, there is analgesia and possibly some decrease in temperature sensation to a level a few segments below the point of chordotomy. There is little if any tactile or other sensory disturbance. There should be no motor loss unless the pyramidal tract is injured. There may be some postoperative edema, giving rise to transient weakness of an extremity, and if this occurs it is on the side of the chordotomy, that is, on the side opposite the one involved with pain. Severe and prolonged paresis occasionally results.

To relieve visceral pain, a deeper chordotomy entering the gray matter is necessary. Care must be taken, however, since too deep a cut anteriorly might catch anterior horn cells and result in muscular atrophy or some tactile disturbance. There is frequently a transient bladder-sphincter disturbance in the form of retention, lasting from a few days to a few weeks and sometimes longer. This is especially true in disease of the pelvis or the bladder wall. It may be related in part to reduction of bladder sensation, or possibly to a damaging of the motor tracts to the bladder, though their location in the cord is unknown. These patients must be catheterized early, and are sometimes put on urinary tidal drainage. In some instances we have done cystometrograms both before and after chordotomy. Because of the resulting analgesia and the poor state of nutrition of many of these patients, pressure spots are prone to develop. This necessitates unusual vigilance in the care of the skin. The pain in the analgesic area may return in a few weeks or after a much longer period. Temperature sense returns quicker than pain sense. Pain sense tends to return more quickly after unilateral chordotomy. It is possible that a few pain fibers may ascend in the homolateral spinothalamic tract.

Despite the possible complications mentioned, chordotomy remains the most reliable method for relieving pain below the neck, and I believe it should be preferred in the presence of intractable pain, unless the patient's condition contraindicates all forms of surgery.

Intraspinal (Subarachnoid) Alcohol Injection

The injection of absolute or 95 per cent ethyl alcohol into the spinal subarachnoid space has been employed with increasing frequency for relief of pain of various types, the procedure was introduced in 1931 by Dogliotti. This method of relief of

pain, especially that in the lower back, pelvis and lower extremities, finds a definite field of usefulness. If the patient's condition contraindicates surgery, if life expectancy is short, if radical relief measures are refused, or if the pain is not too wide spread or severe enough to require chordotomy, spinal subarachnoid alcohol injection may be used with expectation of varying degrees of relief in 60 per cent or more of cases. The procedure is employed in diseases of the cervix, rectum, prostate, bladder, and so forth.

For subarachnoid injection the patient is usually placed on his side with the side involved by disease uppermost, and the hips are slightly elevated so as to permit the alcohol, the specific gravity of which is less than that of cerebrospinal fluid, to rise and bathe the proper nerve roots. A small gauge (No. 22) lumbar-puncture needle is used. A spinal puncture is done, and when cerebrospinal fluid is obtained the injection of alcohol is begun, it must be carried out slowly, consuming two or three minutes, so as to avoid too great diffusion, and also to avoid directing a stream of strong alcohol against one point. The process is virtually free from immediate or later discomfort. There may be a slight amount of root pain, but there usually is only a feeling of warmth or burning in the back, hip or leg during the first part of the injection. Relief if obtained is usually immediate, although occasionally it is somewhat delayed.

The location of the puncture and the amount of alcohol used are important. The second lumbar interspace may be used with success in most cases of low back, hip and leg pain. For pain about the genitals, anus or perineum, that is, pain in the sacral or coccygeal segmental distribution, a lower injection into the third or fourth interspace is preferable. In doing the latter type of injection we have recently been using the technic recommended by Drs. J. C. White and W. J. Mixer of the Massachusetts General Hospital. They advise that the lumbar puncture be done with the patient lying prone with the hips slightly elevated. The puncture is easily done, but it may be necessary to verify the entrance into the subarachnoid space by having the patient cough or by exerting suction with a syringe.

The nerve roots tolerate only a limited amount of alcohol. One may safely use a little more in the lower-level injections. In the second lumbar space from 0.5 to 0.6 cc. of 95 per cent alcohol should be the limit. The use of more is liable to produce sphincter disturbance in the form of bladder retention, which may last for a few days, or even a few weeks or longer. In the third or fourth lumbar spaces from 0.6 to 0.8 cc. may be used. Beyond this, one is liable to induce anal incontinence. Amounts greater than those mentioned may also result in

if the patient had been properly anesthetized by proper nerve section, much more effective treatment could have been carried out. With section, notably that of the fifth and ninth nerves in the posterior cranial fossa, a sufficient area of the throat and face is rendered anesthetic so that extensive local treatment, including surgical excision, the implantation of radium, and so forth, can be carried out without a general anesthetic in addition. This relieves the patient of the fear caused by repeated operations under a general anesthetic, brings him back to the general surgeon for more frequent treatments, gives him a better chance to get rid of his cancer before metastases develop, and provides the surgeon with a much better method of handling this difficult problem.

The possibility of producing anesthesia by neurological methods should be emphasized much more strongly and more frequently than it is. Furthermore, it is an extremely useful adjunct in the treatment of cancer, particularly

that of the face and throat, that should be more widely recognized and more commonly used by general surgeons.

Dr. Hodgson. Regarding spinal subarachnoid alcohol injection, I should say that the method which Dr. White and Dr. Mixer have brought out, where the patient lies prone with his hips elevated, represents an advance in the treatment of pain about the genitals, perineum, lower spine and pelvis. One has to be careful not to elevate the hips too much, because one is liable to concentrate the alcohol rather strongly against low roots and thus produce rectal incontinence. So far as I am concerned—and I have used this method a number of times—I feel that it is unsafe to use as much as 1 cc. of alcohol. From 6 to .8 cc. is about enough, this applies to subarachnoid alcohol injection in general.

Dr. Munro's emphasis on nerve section preceding removal of cancer is to the point, and I believe that this order of procedure should be used more often.

complete or partial relief or failure is difficult to determine, and is influenced by the personal equation. Satisfactory relief can be obtained in about 60 per cent of cases.

262 Beacon Street.

DISCUSSION

DR. ERNEST M. DALAND, Boston. I have followed a good many of the cases treated by Dr. Hodgson, and agree with all that he has said. There are two or three other non-neurological factors in the relief of pain in cancer patients. The first is the very obvious one of surgical hygiene. Most of the pain from an infected and ulcerated carcinoma is due to secondary infection. It is quite extraordinary how much relief can be given by removing slough, using wet dressings, and so on.

The second factor is x-ray treatment. Pain from metastatic carcinoma can be controlled very efficiently by very small doses of x-ray. I refer particularly to bone metastases from carcinoma of the prostate. X-ray is specific for relief in these cases. The relief comes on within a very few days, in most cases of carcinoma of the breast, with bone metastasis, it is very quick and it sometimes lasts for many months.

The third factor is the use of drugs. We have been surprised to see what small doses of medication are required for the relief of pain in patients with advanced cancer. In most patients, mild pain can be controlled entirely by aspirin. We start with this drug, and there is no limit to the amount that can be given. The question is often raised whether or not aspirin will damage the heart. An eminent cardiologist recently said that the only people who were damaged by the use of aspirin were those who were afraid to take it. Following aspirin, we give small amounts of codeine, and combine aspirin and codeine. We insist on using hypnotics for sleep, and not narcotics. Eventually, if the pain increases, opiates have to be given, but always in small quantities, so that in the Pondville Hospital, where Dr. Hodgson does a good deal of this neurological surgery, we find very few people with advanced cancer who require morphine in any considerable quantity. I think that of the patients who die there of terminal cancer, only 10 per cent have had morphine at all, and many have had it not more than once a day.

DR. JAMES C. WHITE, Boston. Dr. Hodgson has spoken briefly concerning the treatment of intractable pain by Dogliotti's method of subarachnoid injections of alcohol. Strange as it may seem, this method carries no greater risk of motor paralysis than chordotomy, but only too often it fails to give adequate relief. I think Dr. Hodgson said that in his experience only 10 per cent failed to get relief, in the cases that have been done on the neurological service at the Massachusetts General Hospital, it has been nearer 30 or 40 per cent. When the pain is bilateral, the risk of failure is far greater.

In asking me to discuss this paper, Dr. Mixter suggested that I outline a new modification of Dogliotti's method that we have been using for bilateral pain, limited to the third, fourth and fifth sacral nerves. This is the type of pain that one finds in inoperable carcinoma of the bladder, prostate, rectum and sometimes cervix. If the growth has remained localized in the neighboring soft tissues and has not spread into bone or into the lumbosacral plexus, it will give pain centered around the anus and deep in the perineum. This may be particularly distressing.

Taking advantage of the fact that alcohol is lighter than

spinal fluid, place the patient in the prone position and elevate the pelvis by lowering both ends of the operating table. The tip of the sacrum and lower end of the subarachnoid space are then uppermost. A lumbar puncture between the fourth and fifth vertebrae or between the fifth lumbar and first sacral, can easily be done in this position, but when the needle enters the subarachnoid space, it is necessary to aspirate in order to get out spinal fluid, because there is not enough pressure with the head down for the spinal fluid to flow out of the needle. If a small quantity of 95 per cent alcohol is injected (we have been using 1 or 1.25 cc.), it will float caudally and infiltrate the third, fourth and fifth sacral nerves. This suffices to produce anesthesia over an area of about 15 cm. around the anus, a little way down the thighs and forward over the perineum, scrotum and penis.

We have used this procedure in 6 cases without any subsequent weakness of the legs. The patients were walking around the next day. In my opinion the reason that it does not produce motor weakness, although it knocks out the pain fibers effectively, is that these fibers are less protected by myelin than the motor fibers, and are therefore more sensitive to alcohol. This procedure may and occasionally does weaken bladder sensation. We have not seen this complication in our cases, but I am sure that we shall in the long run, we have therefore limited its use to patients who either were previously on constant drainage, such as those with carcinoma of the prostate, or had only a short time to live and were willing to go on a catheter regime. This method has been used so far in 2 cases of bladder carcinoma, 2 of prostatic carcinoma and 2 of rectal carcinoma. The injections have caused remarkably little disturbance. After being kept flat overnight, as is done in any routine lumbar puncture, the patients have gotten up, and several have been able to go home the next day. The urological cases were all on constant drainage, so that in these we had no trouble from bladder weakness, but even the 2 patients with carcinoma of the rectum were able to urinate after only one catheterization.

Finally I must mention one other point, that relief may not be permanent, but the injection can always be repeated. Mind you, these were terminal cases. In the case of the longest survival, relief has lasted for six months. Two patients had a recurrence of pain, one of them was re-injected successfully, the other one lived too far away, so his pain continued.

In summary, this method is not intended to supplant chordotomy in patients who are favorable operative risks, but in those who are in too poor condition and who have a very short time to live it is a most satisfactory substitute.

DR. DONALD MUNRO, Boston. Dr. Hodgson's paper is much too important in its relation to the problem of cancer as seen by general surgeons to allow it to go without some comment. Certainly this organization can be considered as being cancer-conscious, at any rate cancer-conscious in relation to the lower bowel. There is therefore no reason to exclude the other forms of cancer from discussion.

One of the methods that can be used much more than it is in the treatment of cancer has to do with the production of a permanent local anesthesia in the region of the cancer. This allows more efficient and painless treatment to be given. It applies particularly to cancer in the neighborhood of the throat and face. I have been consulted about the production of this type of anesthesia in a number of such cases, and have been sorry to observe that in almost every case a long time had elapsed during which,

ment that the pain was somewhat relieved by moving about in bed. I should assume, therefore, that these attacks were not coming from peritoneal irritation resulting from an inflamed viscus. The repeated attacks make me think of some recurrent lesion, and this lends a little weight to the assumption that it has not always been an inflammatory process. Another thing which is of interest is that she had residual tenderness along the course of the colon. When we are dealing with a disorder of a colicky sort, such as gallstone colic, ureteral colic or intestinal colic, we often get a lot of valuable information not only out of the history of the acute attack but also from the fact that there is residual soreness, such as we find over the gall bladder after the pain has subsided and, in the case of ureteral colic, along the course of the ureter. After the acute pain begins to subside we may get a little lead from the localization of the residual tenderness.

Perhaps Dr. Hampton will tell us something about the x-rays.

DR. AUBREY O. HAMPTON. This looks like a twenty-four hour film of the colon, it is the only one that shows anything that resembles a diverticulum—low in the pelvis on the right side. The barium enema shows no diverticulum, or anything else that I can see. Here is one local film that looks like the cecum and terminal ileum, and the ileum appears rather narrow. There is no dilatation proximal to it and the mucosal folds are intact. I do not believe the narrowing means anything. I cannot see anything to account for diarrhea and cramps in the abdomen. The heart is that of a fat person who is fairly old.

DR. SWEET. Is there anything that suggests regional ileitis?

DR. HAMPTON. No, I do not believe there is enough to make a positive diagnosis. The mucosa seems to be intact.

DR. SWEET. Of course we have no reason to suspect regional ileitis in this case except that she had had repeated attacks of abdominal pain, but it was not small-intestine pain.

The description of the pain during the last attack is most interesting. Here we have a woman with an attack of pain coming on very suddenly. We also have the picture of a person who is suffering from a colicky pain, not that of peritoneal irritation. A person with peritonitis, either generalized or localized, lies quietly in bed and resists manipulation. This patient felt better when she moved about, and the story suggests a patient writhing in bed with renal colic or something like that. The fact that the pain bore a relation to severe coughing is of interest but perhaps a little difficult to explain.

The only things we have suggesting infection or inflammation are the elevated white count and the slight increase in polymorphonuclear cells. She had a normal temperature, but that in a patient who had been ill only a short time might be consistent with an inflammatory process, especially at the age of fifty-nine years.

What causes do we have for severe colic such as this? We naturally think of calculus. Did she have gallstone colic? I think not. I do not believe she has ever had gallstone colic, according to this history, because of the fact that the pain has not localized in the gall-bladder region. Unless she had a transposed viscus, with the gall bladder on the left side, I think we can readily rule that out. Renal colic will give a picture similar to this. Not infrequently people have ureteral stone which results in abdominal cramps. I have seen several patients and heard of others who were thought to have symptoms indicative of acute intestinal lesions, but who had nothing but renal calculi. We observe that her urine was negative, and that she had, on her second admission, a mass in the abdomen that would be hard to explain on the basis of renal origin unless she had an abnormally located kidney with an intermittent hydronephrosis. So, I believe we can exclude a renal origin for the pain.

What other causes of colic do we have? Did she have small-bowel obstruction? I think not, the pain is not described as being in the location where one would have referred pain of small-intestine origin.

Did she have obstruction of the large intestine—a sudden transitory affair? That is a very definite possibility. She might have had intermittent attacks of volvulus of the sigmoid or intermittent attacks of intussusception. But against that, she never manifested blood in the stools and there is no evidence of anything to incite intussusception, such as tumor or polyp.

Did she have diverticulitis of the sigmoid? Dr. Hampton has pointed out one site of a diverticulum. I should be inclined to omit that in the differential diagnosis because of the fact that the pain was so sudden in onset and because of the character of the pain, although of course we do have the fact that with the second attack she had local tenderness over the mass which was in the region of the sigmoid. All things considered I feel that she did not have diverticulitis of the sigmoid. Before we finish talking about the intestinal tract, we should consider the possibility of one of those rare internal hernias with a loop of intestine caught in a peritoneal fossa which might give her a sudden attack of intestinal obstruction. We have no evidence for it. It might be difficult to explain the tumor on that basis, but such a le-

CASE 24081

PRESENTATION OF CASE

First Admission A fifty-nine-year-old American housewife entered the hospital with the complaint of recurring attacks of abdominal cramps occurring over a period of eight years.

During the ten years before entry she had had six or eight attacks of generalized abdominal cramps with some nausea and occasional diarrhea, but no vomiting. The attacks occurred at irregular intervals, lasted three to four days and were relieved by rest in bed, a simple diet and sedatives. She did not pass blood, pus or mucus by rectum. Three days before entry she had another attack which consisted of severe cramps, severe diarrhea and some nausea, but no vomiting or fever.

Her past history and family history were noncontributory. At the age of twenty she had weighed about 135 lb., and her weight had gradually increased until the time of entry, when she weighed about 180 lb. Her menstrual history was negative, with a normal menopause at the age of fifty.

Physical examination revealed an obese woman complaining of cramplike pain in the abdomen. There was generalized abdominal tenderness which seemed to follow the course of the colon. There was no tenderness in the region of the gall bladder, and no icterus. The pain was somewhat relieved by the patient moving about in bed.

The temperature was 98.6°F., and the respirations were 20.

The urine examination was negative. The blood showed a white-cell count of 11,100 with 65 per cent polymorphonuclears.

An x-ray of the chest showed the heart shadow to be slightly enlarged downward and to the left. The aorta was tortuous and prominent in the region of the knob, and the diaphragm was a little high on both sides and moved normally with respiration. The lung fields were clear. A gastrointestinal x-ray series and a barium enema were negative. A Graham test showed only a faint shadow of the gall bladder with many ringlike shadows in it which had the characteristic appearance of gallstones.

She was discharged after a week in the hospital

and went home on a regime including a low calorie, low-residue diet, frequent rest periods, and improved bowel hygiene.

Final Admission (nine months later) She was well until eight months after discharge, when she had a bad head cold. This cleared furly promptly but left her with a severe cough. Three weeks later she noticed pain in her left lower quadrant which occurred only on coughing and lasted for a few minutes, but was severe enough to justify calling her physician. Four days later she suddenly developed very severe pain in her left lower quadrant which came on during a coughing spell and persisted. One hour later she was seen by her physician who found her bent over the back of a chair moaning with severe pain in the left lower quadrant. The pain was constant, but somewhat spasmodic, coming and going in waves, although she was never entirely free from pain. It was so severe that she could not lie quietly in bed. It was difficult for her to straighten up, and she preferred to remain somewhat bent over. She had no nausea or vomiting.

Physical examination revealed nothing abnormal in the heart and lungs, the blood pressure was 120 systolic, 80 diastolic. Marked spasm and tenderness were noted in the left lower quadrant over an area about the size of a man's hand. The tenderness was so acute that the examination was not entirely satisfactory. There was an indefinite feeling of a mass about the size of a grapefruit in the region normally occupied by the sigmoid, which extended up to the level of the umbilicus and down to the brim of the pelvis. Pelvic examination revealed an atrophied cervix. There was no tenderness in the vaults, and the fundus could not be felt, manual examination was impossible because of pain. The rectal examination was unsatisfactory because of hemorrhoids.

The temperature was 98.6°F., the pulse 100. The respirations were 20.

The blood showed a white-cell count of 17,400 with 80 per cent polymorphonuclears. The urine examination was negative.

She was given a subcutaneous injection of Panto-pon which gave her no relief. Two hours later the white-cell count was 16,000, and shortly thereafter an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. SWEET It is interesting to note that the pain was colicky. It was a cramp-like pain, not a steady one, and therefore tends to make us believe that she was not suffering primarily from an inflammatory process. Another thing which more or less bears this out is the state-

from below. However, this diagnosis would have explained everything—the suddenness of onset, the severe pain, the mass, and the white count. I will say this, that when she had spinal anesthesia the mass felt quite different from what it had before and we got our first true suspicion of what might be the matter, it then felt as if it were definitely in the abdominal wall and not within the abdominal cavity. When we opened her rectus sheath we found a large hematoma. She had ruptured her deep epigastric artery and had bled profusely into the abdominal wall.

DR. MALLORY. We have a significant number of cases every year in which lesions in the abdominal wall are mistaken for intra-abdominal disease and it seems worthwhile reminding people occasionally of the possibility

CASE 24082

PRESENTATION OF CASE

A twenty-four-year-old American housewife entered the hospital complaining of pain and swelling of the left knee of four years' duration.

About four years before entry, two months after her marriage, the patient first noticed pain and swelling of her left knee which lasted for two weeks and subsided spontaneously. At the birth of her first child a number of months later she had a similar attack lasting two or three days. She had no further symptoms until twenty-three months before entry when she noticed that her knee became painful after much use. Eighteen months before entry x-rays were taken by her physician and she was advised to have her teeth extracted, which gave her no relief. Six months before entry the pain had become so severe that she was forced to discontinue her work at a shoe factory. The application of heat to the knee caused an exacerbation of the pain. For the two months before entry she had had to use crutches, and a cast had been applied without relief shortly before she came to the hospital. Her general health had been good, but her weight had fallen from 154 to 126 lb.

Her family and past histories were noncontributory.

Physical examination revealed a well-developed

and nourished woman in no apparent discomfort. Her heart, lungs and abdomen were negative. Her blood pressure was 124 systolic, 76 diastolic. There was thickening of the periarticular structures about the left knee with swelling, heat and tenderness, most marked over the region of the internal femoral condyle. The knee was not reddened. There seemed to be a slight excess in the amount of fluid, but ballottement of the patella was unsatisfactory because of pain. No definite fluctuation was detected, and no involuntary spasm could be made out. There was a flexion deformity of 30°, and the range of motion was from 90 to 130°, with both limits marked by pain. The knee jerk was normal.

The temperature was 99°F., the pulse 100. The respirations were 20.

The urine examination was negative. The blood showed a white-cell count of 9400 with 69 per cent polymorphonuclears, and a hemoglobin of 85 per cent. A tuberculin test using a 1:500 dilution was positive, but the 1:5000 and 1:10,000 dilutions were negative. The serum calcium was 11.65 mg per cent, and the phosphorus was 4 mg per cent. The blood Hinton test was negative. A lumbar puncture was negative. No gram-negative diplococci were seen in a vaginal smear.

X-rays of the knee showed a rather extensive process involving the lower portion of the shaft of the femur. There was spur-like formation of the periosteum along its medial side and onion-layer periosteal thickening along the lateral side, producing a widening of the shaft of the femur from the lower border of the articulating surface to the level of the top of the accessory joint space. There were multiple areas of mottling within the shaft of the bone, with destruction of considerable portions of the cortex. There was very little bone atrophy, there was considerable soft-tissue shadow in the region of the upper portion of the joint capsule, but it could not be determined whether it was within the capsule or external to it. The articulating surfaces were smooth, and there was no widening of the joint space. X-rays of the chest were negative.

On the ninth day an attempt was made to aspirate the knee, but nothing was obtained. Four days later an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. ERNEST M. DALAND. The first thing to settle is whether this was an inflammatory condition in the knee or joint, or whether it was a neoplasm. Four years before entry she noticed pain which subsided within two or three days. She went along for a number of months and had pain again for two or three days, and five months later had some

sion ought to be mentioned in a complete discussion of the possibilities

Is there anything connected with the pelvic viscera which might have caused these symptoms? I doubt it very much, because she has had a history of such long standing, with many attacks of pain of this same sort. If this were due to a cyst or a pedunculated fibroid with twisted pedicle or some other such source, I should expect that someone would have operated and removed the offending organ during one of the previous attacks. So I doubt that this is a cyst with a twisted pedicle or a pedunculated fibroid, although with this type of story we might very well make that diagnosis, especially with the elevated white count and relatively low temperature. I presume that it will be next to impossible for me to make the correct diagnosis in this case, but I have a feeling that the suddenness of the onset of the attacks and the fact that she has had previous attacks of a similar nature suggest that there is some mechanical obstruction to some viscus which has been repeated in the past and is perhaps the cause of the present difficulty. Considering the type of the pain, the location of the pain, the past history and the presence of tumor in the left lower quadrant in the region of the sigmoid, it would be reasonable, though probably not correct, to say that she had had a volvulus of the sigmoid, and I make that my diagnosis.

DR WILLIAM B BREED I should like to ask Dr Hampton if he could rule out a diverticulum, which had produced symptoms nine months previously, as a cause of her present symptoms.

DR HAMPTON I think that the absence of diverticula is good evidence that it was not diverticulitis. We have seen one or two rare cases of diverticulitis where we did not see diverticula, the patients had only one or two in the whole colon and these were obliterated by disease. I think it is probable that such cases could not be diagnosed by x-ray examination.

DR WYMAN RICHARDSON It is interesting that her attacks of pain started with a cough, and I wonder, with the temerity of a medical man, if this is not strangulated hernia. Can they not go up instead of down?

DR. SWEET Yes, that is why I thought of intestinal strangulated hernia. It is a very rare lesion.

DR TRACY B MALLORY We have broken a precedent in this case because we ordinarily take up only cases from which some specimen has reached the laboratory as objective evidence of the diagnosis. In this case there was no specimen to examine. Dr Allen can tell us about what he found and perhaps will discuss his preoperative diagnosis.

DR ARTHUR W ALLEN I saw this woman in

the middle of the night and had a hard time coming to any conclusion about what was the matter with her. I finally arrived at the same diagnosis that Dr Sweet has made. She was a short, fat person and difficult to examine. I tried to connect her present illness with her past history and that is where both Dr Sweet and I fell down, because her present illness had nothing whatever to do with the preceding attacks of which she had complained. What they were due to, I have no idea—perhaps to dietary indiscretion.

The first thing that occurred to me when I saw her was a strangulated hernia. I think it is not always possible to be sure you are not dealing with strangulated interstitial hernia, but this mass was much too tender for one thing. It did not feel like any strangulated hernia that I had ever seen, and it was in the wrong location. It was well above the inguinal region and not far enough out in the flank to be one of those peculiar hernias that occasionally occur there. There is one thing not given in the history which it is only fair to state, and that is that bimanually one could be almost certain of being able to ballot this mass between the examining hands. I recall this fact quite distinctly.

The suddenness of the onset made me feel that it had to be a mechanical affair, and I had a hard time explaining the white count on the basis of the diagnosis that I made. I should be surprised if a torsion of the sigmoid would give a white count of 17,000 in a matter of hours. Her symptoms started at seven or eight o'clock at night, and I saw her shortly after midnight. I thought her white count might be in some way related to her upper-respiratory-tract infection, which she still had. The other thing that Dr Sweet did not mention and that I very seriously considered was whether her three weeks of some sort of illness with fever and so forth might have been due to an acute inflammatory gall bladder and that the gall bladder had eroded into the intestine and produced a gallstone ileus. We got out the x rays that had been made nine months previously and did not believe that her stones were large enough to produce obstruction, and besides, the character of the onset was not typical of gallstone ileus. I have never seen such a patient who did not vomit. Of course they do not occur every day, but when they do there is usually a story of vomiting with the obstruction, which is usually very definitely of the small-bowel type, and as a rule you do not feel a mass.

The question of twisted ovarian cyst was very carefully considered, and we felt that that probably was unlikely on the basis that this mass felt much too superficial. You could get at it too easily.

PREOPERATIVE DIAGNOSIS

Neoplasm of the left femur

DR DALAND'S DIAGNOSIS

Ewing tumor of the femur

ANATOMICAL DIAGNOSIS

Lymphosarcoma of the left femur

PATHOLOGICAL DISCUSSION

DR. MALLORY This case is a good illustration of the truth of Dr. Codman's remark about Dr. Taylor's case several weeks ago: if the clinicians and radiologists cannot make a diagnosis it is generally pretty difficult for the pathologist to make one. It is fairly easy to rule out certain things. It certainly is not an osteogenic sarcoma or a Ewing tumor. It falls in the general group that we include in the diagnosis of lymphoma, but when it comes to subclassifying it further we begin to get a difference of opinion. We classified this, and I think all of us are still ready to stick by it, as a primary lymphosarcoma. Dr. Frederic Parker, Jr., has, I believe, seen the sections and is inclined to think it is Hodgkin's disease of the sarcomatous type. He believes that true lymphosarcoma probably never appears primarily in bone. It is true there are a few multinucleated cells here which are indistinguishable from those seen in Hodgkin's disease, but they represent a very small proportion of the tumor cells. The great majority of them look like lymphoblasts and young lymphocytes. This patient also has been followed over a period of three years and when last seen was free from recurrence.

Dr. Simmons, would you be willing to say a

word about the duration of life of these bone-tumor cases?

DR. SIMMONS I have recently been reviewing the cases of osteogenic sarcoma and other malignant tumors primary in long bones that were seen in this hospital from 1920 to 1932. In this period there were 34 cases which were operated on, and I was much surprised to find that 11 were living without evidence of disease five or more years after operation. This proportion of 30 per cent five-year cures is much higher than the usual figures given for the curability of osteogenic sarcoma. It seemed worth while, therefore, to try to analyze the material further in an attempt to find some factor which might bear upon the question of prognosis. The osteogenic sarcomas could, apparently, be divided into two groups: one of rapidly growing tumors containing very pleomorphic cells, the second of tumors consisting predominantly of fibrous tissue or well-formed cartilage. None of the first group lived, whereas there were 9 survivors among the second. Another group of malignant tumors primary in bone which can be cured are the reticulum-cell sarcomas. There were 2 such cases in this series. One was operated on in 1924. In 1931 a massive recurrence developed in the soft parts above the operative stump. This was removed and the patient is perfectly well seven years later. A second case was operated upon in 1921 and died in 1935, fourteen years later, of a tumor in another bone. All the cases of Ewing sarcoma, of which there were 9, are dead. Our experience, here, is certainly different from that of other hospitals such as, for instance, the Children's Hospital. Their experience has led them to believe that osteogenic sarcoma is a uniformly fatal disease.

teeth extracted. It is a question whether this knee condition dates back the full four years or whether in retrospect some unrelated episodes were picked out of her history. Her physician apparently thought she had an inflammatory knee and advised extraction of the teeth. The loss of weight is significant. The thickening of the periarticular structures, the cell count and the tenderness over the internal femoral condyle are also very significant. We should pay attention to the local heat and tenderness, although there was no redness of the skin. It was believed that there was some fluid in the joint, but the history tells us that when the knee was subsequently aspirated no fluid was obtained. I call your attention to the fact that she had a temperature of only 99° , which is against infection. The white count was 9400 and the smear contained 69 per cent polymorphonuclears, that is very definitely against an infection. We have nothing to lead us to think that she had an osteomyelitis, and the low white count and polymorphonuclears are definitely against it. The possibility of tuberculosis involving the knee joint was considered, and the tuberculin test, using a 1:500 dilution, was positive. I think that can be thrown out as not significant in view of the fact that higher dilutions were negative. The calcium and phosphorus metabolism was apparently normal, which helps us to rule out a parathyroid condition. I think that we have no reason to believe there was an acute periarticular inflammatory arthritis, although that was apparently considered since a vaginal smear was done in a search for gonococci.

We come down to the x-ray examination with a very definite feeling that her trouble is due to a neoplastic condition rather than to an inflammatory one. The x-ray examination shows a single lesion in the lower end of the femur, which is characterized by both destruction and proliferation of the cortex and by the absence of any definite soft-tissue tumor. There was thickening, seen best in this film, which was probably in the capsule of the joint. The joint surfaces, however, were smooth, and the joint spaces of normal width. If this thickening were due to either tuberculosis or any other infection, I should expect more changes in the joint itself, but tumor may infiltrate a joint capsule and in that case you might get such a picture as you see here. The extent of this tumor up the shaft of the bone is considerable, yet it has not gone through the cortex completely, in other words it does not look like a primary osteogenic tumor, but here again it may belong with the irregular group. I do not believe that we have to consider tuberculosis or osteomyelitis very seriously. Syphilis should always be thought of in such a condition, but I do not consider that very seriously here.

Before seeing the x-ray I was inclined to think it was osteogenic sarcoma. The other possibility is a Ewing tumor. We do see here a little of the onion-layer appearance which, if it were more distinct, would be definitely in favor of Ewing tumor. There is no ray formation, which would be more suggestive of osteogenic sarcoma. As to age,—this woman was twenty-four,—she falls into the late group of those having a Ewing tumor and into the middle of that of those with osteogenic sarcoma, the latter usually occurring between the ages of twenty and thirty. We think of people under twenty as belonging to the Ewing group, and over twenty to the osteogenic class. The absence of a soft-tissue tumor, even with a story going on for two or three years, is definitely against an osteogenic sarcoma. The slight rise in temperature, the slight rise in white count and the local heat are more in favor of Ewing tumor, although we ordinarily see more of a rise in temperature and are rather more apt to see a white count of 12,000. I believe there is nothing suggesting a cystic condition such as osteitis fibrosa cystica or a solitary cyst. About half of all osteogenic sarcomas recorded in the literature occurred in the lower end of the femur. This is a region where we should expect to find either a Ewing tumor or an osteogenic sarcoma, but not metastatic cancer. Metastases are much more apt to appear in the upper part of the femur in the subtrochanteric region, and this woman was a little young to expect metastatic cancer, so the diagnosis is unlikely although it cannot be absolutely ruled out. Nothing here suggests any other trouble and my feeling is that this is a Ewing tumor.

DR TRACY B. MALLORY: Dr Simmons, have you any comment to make?

DR CHANNING C. SIMMONS: I am not sure but I believe I know the case. Although I should agree with Dr Daland that the tumor is not metastatic, I do not believe it is a Ewing tumor. It is a tumor of long duration, if the history is correct. The Ewing tumor ordinarily involves the shaft rather than the lower end of the bone. It is a bone-destructive rather than bone-formative tumor, and this case shows both. Although Ewing tumor in the later stages can cause a great deal of secondary bone formation, it is usually not infiltrative. The mottled appearance is not at all inconsistent with malignant lymphoma or reticulum-cell sarcoma. We have no record of a differential count. I do not know whether it would help us. The phosphatase value is not mentioned. My feeling would be that it probably is a tumor of the group of reticulum-cell sarcoma or lymphoma rather than primary bone tumor.

other a person with civic and executive experience" While it is true that some question as to the qualifications of these two commissioners was brought up at the legislative hearing on the proposed bill, the members of the Special Commission were unanimous in supporting the bill, which reads, in part, as follows

The commissioner and the first associate commissioner shall be physicians who are diplomats in psychiatry of the American Board of Psychiatry and Neurology, Incorporated, and shall have had at least seven years experience on the staff of a state or federal hospital for mental diseases or in any equivalent psychiatric organization. The second associate commissioner, if not qualified as aforesaid, shall be a physician who has had at least seven years experience on the staff of a hospital for general medical and surgical cases.

The *Journal* is of the opinion that it would be very difficult to find an expert psychiatrist who, at the same time, would be either a well-trained engineer or an able steward—such a feeling is also implied in the proposed bill. As the construction and physical maintenance and the house-keeping problems of institutions connected with the Department of Mental Diseases, or the proposed Department of Mental Health, are of utmost importance to the proper functioning of the department, it seems advisable that well-qualified and well-trained experts in these particular aspects of mental hospital care should have extremely responsible positions therein.

In view of the *Journal's* stand in regard to the dangers of overcentralization of power, it is gratifying to be informed that the section of the bill recommending that the power of appointment of the medical personnel and other employees should be transferred "from the trustees to the department" should read "from the trustees to the superintendents." The mistake is said to be due to technical errors in the preparation of the draft.

At a recent meeting of the Committee on State and National Legislation, the members recommended unanimously that the bill be supported by the Massachusetts Medical Society.

CASE HISTORY No. 60 PREMATURE SEPARATION OF THE PLACENTA

Mrs. T. B., a white, twenty-three-year-old primipara, seven and a half months' pregnant, was advised by her physician to go to the hospital on May 20, 1937. While at dinner, she had experienced some low abdominal discomfort, which was followed two hours later by staining. An hour later she began to flow, with increased discomfort.

The family history was essentially negative. There was no history of scarlet fever, diphtheria, rheumatic fever or chorea. At thirteen the patient had had pneumonia, at fourteen her appendix had been removed, and at nineteen her tonsils and adenoids. Catamenia began at thirteen and were of the twenty-eight-day type, lasting five days without pain. Her last period was October 1, 1936, making her due July 7, 1937.

She had consulted her own physician at the very beginning of this pregnancy and had been seen routinely since then. Her blood pressure at routine visits had averaged 120 systolic, 68 diastolic. There had been no edema, and the urine had been negative except for a very slight trace of albumin during the first two months. The patient was last seen ten days previous to entrance to the hospital, at which time her examination was normal, and the blood pressure 122 systolic, 90 diastolic.

The patient was admitted to the hospital after a journey of eighteen miles by automobile. At the time of entrance she was flowing moderately. The pain in the abdomen had increased since her telephone conversation with the doctor and was very severe. The baby was active.

On physical examination the patient was well developed and nourished. Her pupils were equal and reacted normally. Mouth and throat were normal. The heart showed no enlargement, there were no murmurs. The lungs were normal to percussion, there were no rales. The abdomen was symmetrically enlarged by a pregnant uterus of approximately seven and a half months' size. The uterus was in contraction, was very tender to

A series of selected case histories by members of the section will be published weekly.

improvement fails to occur. The information gained in this way is one of the best guides in determining dosage in the serum treatment of pneumonia.

Blood cultures are also valuable in verifying the type of pneumococcus responsible for the infection. When a sputum sample is unsatisfactory and pneumococci are scarce, there is great danger that the typing report may represent a throat organism and not one causing infection in the lung. This fact may sometimes account for apparently poor results in serum therapy. If the pneumococci in both the blood culture and the sputum are identical, serum therapy can be continued with confidence that the proper type is being used.

The Massachusetts Department of Public Health announces in another column that arrangements are being made to have a number of additional laboratories undertake to examine blood cultures taken from pneumonia patients. This increase in the availability of the procedure should make it possible for physicians to follow their cases much more closely and should result in the saving of additional lives by the use of serum. The further announcement that arrangements are being made to compensate laboratories for tests done on patients who are unable to pay should also be welcome to physicians who have had difficulties in the past in arranging for laboratory work on such individuals.

BLOOD CULTURES IN PNEUMONIA

RECENT experience in treating pneumonia with specific serum has demonstrated the great usefulness of determining whether the pneumococci have invaded the blood stream. Cases showing positive blood cultures usually follow a stormy course and are much more likely to end fatally than those in which the pneumococci are never found in the blood stream. To save life in the presence of bacteremia much larger doses of serum must be used. At least one blood culture should be taken on every patient treated with serum, and repeated cultures should be made on those in whom prompt

DEPARTMENT OF MENTAL DISEASES—A CORRECTION

It has been called to our attention that an error was made in the editorial "Department of Mental Diseases" which appeared in the February 3 issue of the *Journal*. In speaking of the qualifications of the commissioners of the proposed Department of Mental Hygiene, as submitted by the Special Commission, it was stated "Of the other two [the second and third commissioners], one would be a physician, not necessarily a psychiatrist, and the

the touch, and showed no relaxation at any time. The fetal heart sounds were heard at the rate of 140 per minute. By rectal examination the cervix was found to be long, firm and undilated, there was no evidence of placenta previa. A consultant was called who agreed that the diagnosis was early separation of the placenta and that the procedure of choice was cesarean section.

A low transverse cervical cesarean section was performed. The uterus was firmly contracted around the fetus, and there was slight discoloration in the lower uterine segment near the left broad ligament. The baby was extracted without difficulty, breathed immediately, and weighed 4 lb, 9 oz. The placenta on removal showed a small area, approximately 5 cm in diameter, near the lower border which was discolored by dark adherent blood clots. The uterus contracted well after the operation. The patient made an uneventful recovery, and the baby was 6 oz above the birth weight on discharge from the hospital.

Comment. Cases of premature separation of the placenta occur without definite etiology. Some separated placentas occur with toxemia, others are certain to follow direct trauma, but neither was present in this particular case. The diagnosis of partial separation of the placenta in this case was based upon the firmness of the uterus, the presence of the fetal heart, and a rectal examination which did not reveal a placenta previa. Cesarean section on cases of partial separation of the placenta, where the baby is viable and the patient not in labor, is becoming the accepted method of delivery. Had this baby been dead, the more conservative procedure of rupturing the membranes, packing the cervix and applying fundal pressure would have been the operation of choice. Had the patient been in labor with either a dead or a living child, vaginal delivery should have been considered. Were the cervix soft and dilatable, rupturing the membranes and allowing labor to proceed would be the procedure of most men. The old-fashioned accouchement forcé,—manual dilatation of the cervix,—is an operation which is never done today. The cervix cannot be treated with too much respect, and manual dilatation of any cervix that is not obliterated, soft, and dilated at least three or four fingers is to be condemned.

NOTICE TO FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY

THE *New England Journal of Medicine* is sent to all fellows whose dues are fully paid. After March 1, delinquent fellows are dropped from the mailing list. All fellows are urged to remit their

dues for the current year to their district treasurers before March 1.

operations were done. Two hundred and fifty babies were born in the hospital.

Dr Sven Gundersen was the guest speaker at the annual meeting of the Belknap County Medical Society. His topic was "Serum Treatment of Pneumonia."

DEATHS

SISKE—HARRY E. SISKE, M.D., died at the Hanover Hospital on November 2. He was born in Monson, Massachusetts, in 1877, and was graduated from Monson Academy and Tufts College Medical School.

He had been employed as a physician at the State Hospital in Concord, at the Penal Institution at Providence, Rhode Island, and at the Memorial Hospital in Pawtucket, Rhode Island. He had also been roentgenologist at St. Joseph's Hospital, Providence, Rhode Island. At the time of his death Dr Siske was assistant superintendent at the New Hampshire State Sanatorium at Glenduff.

In 1927 he was married to Ethel Bennett Stubbs of South River, New Jersey.

Dr Siske was a member of the Grafton County and New Hampshire medical societies.

PLATTS—HARRY S. PLATTS, M.D., of Troy, died on January 5. He had practiced medicine in Troy for more than thirty-five years.

Dr Platts was born in 1876. He was graduated from the Dartmouth Medical School in 1898, and was a member of the New Hampshire Medical Society, the Masonic Order and the American Legion.

LUNDERVERVILLE—EVERETT P. LUNDERVERVILLE, M.D., died February 4 at his home in Berlin. He was born in 1874 at Enosburg Falls, Vermont, the son of Mr and Mrs Matthew Lunderville.

Dr Lunderville graduated from the University of Vermont College of Medicine in 1896. He was also a registered pharmacist. Before going to Berlin twenty years ago, he practiced medicine in St. Albans and Richford, Vermont. He was married to Hortense Virginia Paquet in St. Albans, Vermont, in 1900.

Dr Lunderville is survived by his widow, one daughter, Mrs. Everett J. Carney, of Bellows Falls, Vermont, one brother, and two sisters.

VERMONT STATE MEDICAL SOCIETY

MAURICE—GEORGE B. MAURICE, M.D., of Waterville, Vermont, died November 30, 1937. He was in his sixty-fifth year.

Born in Waterville, Vermont, the son of Daniel F. and Mary P. Maurice, he received his early education there. He received his degree from the University of Vermont College of Medicine in 1899 and had practiced in Waterville for nearly forty years. Dr Maurice was a member of the Vermont State Medical Society.

His widow survives him.

MISCELLANY

DR. JAMES MINOT HONORED

At the annual meeting of the Boston Tuberculosis Association held February 15 a new office was created, that of honorary president, and Dr James J. Minot, of 188 Marlboro Street, Boston, who was a founder of the Association in 1903, was elected to fill this office. In making the nomination Dr Reginald Fitz spoke as follows:

On April 21, 1903, at the suggestion of Dr Minot, a

group of gentlemen met in the library of his Boston home to form the Boston Association for the Relief and Control of Tuberculosis. In this manner our Society originated. Ever since that day Dr Minot has given, continuously, enthusiastic and imaginative service to the Association. In the early days, his efforts were largely instrumental in bringing it about that tuberculosis in Boston was made a reportable disease and it became possible to discover how many cases there were in the community and how significant was the tuberculosis problem. Presently he organized a day camp on Parker Hill for the care of tuberculous patients. The Boston Sanatorium is an outgrowth of this action. He then helped to develop outdoor schools for tuberculous children and methods for stamping out tuberculosis by examining contacts. He became influential in developing municipal health clinics where cases were followed or where individuals suspected of harboring tuberculosis were skillfully examined and in establishing laboratories wherein the diagnosis of tuberculosis was made scientifically. He was soon recognized as a pioneer in educating the public in regard to the menace of tuberculosis and in enlisting public interest in the fight against it. As time went on he became increasingly impressed with the necessity for preventing tuberculosis. Hence, nutrition clinics for delicate children grew up in our schools and the Prendergast Preventorium came into being. He has helped to raise large sums of money to fight tuberculosis, money raised from a host of small contributions through the selling of Christmas Seals each year and through certain individual citizens who have contributed to the cause in a more significant manner from time to time because of his honest, dogged pleading. In brief, for thirty-five years without interruption, Dr Minot has set the pace toward wiping out the menace of tuberculosis in Boston. He has done all in his power to improve methods of diagnosis and treatment for the ill so that they might be cured, and to forestall the development of the disease in those who were not ill by sensible means of prevention. Since 1919 he has served our Association as vice president. It is the well-considered opinion of the Executive Committee that after so long a term of service a more disjunctive office should be made for him. The Executive Committee wishes to have the benefit of his counsel and inspiring influence in its work, on the other hand, the committee does not wish to overload him with administrative details. Therefore, the committee asks that a new office in the roster of the Association be created that of honorary president. To fill this office, it is my privilege to bring before you for consideration the name of James Jackson Minot. I move that the members of the Boston Tuberculosis Association signify by a rising vote their unanimous assent to the election of Dr Minot as their honorary president.

HARVARD UNIVERSITY APPOINTMENTS

Dr Kurt Goldstein, head of the neurophysiological and psychopathological laboratory of the Montefiore Hospital, New York City, has been appointed William James lecturer on philosophy and psychology at Harvard University next year.

Teaching and research staff appointments include the following: Eric G. L. Bywaters, of London, England, research fellow in medicine; Eugene R. Sullivan, of Fall River, Henry P. Walcott Fellow in Clinical Medicine; Adolph L. Saks, of Iowa City, Iowa, research fellow in neurology; Unto U. Uusila, research fellow in physiology and anatomy; Volta R. Hall, Jr., of Cleveland, research fellow in psychiatry; Joseph L. Lewis, of Dorchester, as-

Pediatrics Chairman Dr Warren R. Sisson Instructors Drs Robert H. Aldrich, James M. Baty, Benjamin W. Carey, Jr., Stewart H. Clifford, Louis K. Diamond, R. Cannon Eley, Leroy D. Fothergill, Harold L. Higgins, Henry W. Hudson, Jr., Donald W. MacCollum, Patrick J. Mahoney, Charles F. McKhann, Edwin H. Place, Eli C. Romberg, Clement A. Smith and Conrad Wesselhoeft.

There will be a presentation of cases in the sessions on rheumatic fever and heart disease wherever it is feasible. All courses will be aided by new lantern slides, many of which are in natural color. The faculty have prepared an unusually fine teaching exhibit which should be interesting to every physician.

* * *

The following sessions are arranged for the week beginning February 28

ESSEX SOUTH

Tuesday, March 1, at 4 00 p m., in the Nurses Home of the Salem Hospital, Salem. Subject Early Syphilis. Instructor Rudolph Jacoby. Walter G. Phupen, *Chairman*.

MIDDLESEX EAST

Tuesday, March 1, at 4 00 p m., at the Melrose Hospital, Melrose. Subject Drug Therapy in Pediatrics. Instructor Warren R. Sisson. Joseph H. Fay, *Chairman*.

NORFOLK

Friday, March 4, at 8 30 p m., at the Norwood Hospital, Norwood. Subject Treatment of Burns. Instructor Henry W. Hudson, Jr. Hugo B. C. Rierner, *Chairman*.

NORFOLK SOUTH

Monday, February 28, at 8 30 p m., at the Quincy City Hospital, Quincy. Subject Pneumococcus Pneumonia and Serum Therapy. Instructor Joseph H. Pratt. David L. Belding, *Chairman*.

PLYMOUTH

Tuesday, March 1, at 4 00 p m., in the Rosa Field Nurses Residence, Brockton Hospital (rear of hospital), Brockton. Subject Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor Paul D. White. Walter H. Pulsifer, *Chairman*.

WORCESTER (Milford Section)

Thursday, March 3, at 8 30 p m., in the Nurses' Home of the Milford Hospital, Milford. Subject Septicemia. Instructor Christopher J. Duncan. Joseph Ashkins, *Chairman*.

NEW HAMPSHIRE MEDICAL SOCIETY

NEW HAMPSHIRE HEALTH NOTES

The expansion of health services made possible by social security funds is still in the development period. It is safe to say that the services of every division have increased for the common good, and that new services have been made possible in all divisions.

The Maternal and Child Health Division now has a medical director. Increased personnel has made possible better and more universal service, state wide in scope. The

maternal mortality has reached a new low in 1936, being 481 per 1000 births (urban 605 and rural 320). Maternity centers are conducted in Concord, Berlin, Portsmouth and Goffstown.

The Crippled Children's Division is new in the State Health Department. The 1936 legislature appropriated \$11,000 for this service, which, matched by federal funds, provides for care of crippled children under twenty-one years of age. On the State Register at the end of September, 1937, were listed 1060 children. There is plenty of work to be done in this service and many uses for this appropriation. The State clinic is held at the New Hampshire Memorial Hospital, Concord, the second Thursday of each month, there are an orthopedic surgeon, a neurologist, and a pediatrician in attendance.

SERUM TREATMENT OF PNEUMONIA

It has been announced by Dr. Travis P. Burroughs, secretary of the New Hampshire State Board of Health, that plans are being made concerning pneumonia control throughout the state, especially as regards the providing of free serum. At the present time, the laboratory of the Board of Health in Concord is doing Neufeld typings at any time of the day or night on sputum that is brought to it by messenger. The results are reported immediately, and if the case is treatable, a sufficient quantity of serum is given to the messenger with absolutely no cost.

The only laboratory authorized to do sputum typing for pneumonia and to provide free serum is the State Laboratory at Concord. The reports of typings done at other laboratories are not accepted. However, plans are being made to provide centers all over the state where a competent technician will be present at all times and where serums will be available for the treatable types.

PERSONALS

Dr. Timothy F. Rock, of Nashua, is New Hampshire chairman of Tufts College Medical School campaign. The new sound film, "The Family Doctor," is being shown in various parts of the state under Dr. Rock's direction.

Dr. William M. Prince, formerly university physician at Durham, has opened an office for the general practice of medicine. Dr. W. G. McGregor is temporarily in charge of the university infirmary and Hood House.

Miss Myrtle Flanders, because of poor health, has resigned her position as head of the New Hampshire Chapter of the American Red Cross. Miss Ruth Kernodle will represent the national organization.

Dr. W. J. Paul Dye, of Wolfeboro, has given several lectures on surgical topics before service club and women's organizations during the past four months.

Dr. Elizabeth G. Samoylenko, formerly on the staffs of the Massachusetts General Hospital and the Massachusetts Eye and Ear Infirmary, has opened an office for the practice of urology at Manchester.

Dr. Ludwig Mendelson has opened an office for the practice of surgery and gynecology at Dover.

NOTES

At the annual meeting of the Laconia Hospital Association, Miss Lilian G. Williams, superintendent, reported the most active year in the history of the hospital. Over 2000 inpatients were treated in 1937, with a total income of \$133,903, and expenditures of \$133,360. Over 1400

SUSPENSION OF LICENSE

To the Editor This is to inform you that at the meeting of the Board of Registration in Medicine held February 10, 1938, it was voted to suspend for one month the license of Dr. Edward Fenun, 236 Seaver Street, Dorchester, Massachusetts, because of his testimony in court.

STEPHEN RUSHMORE, M.D., *Secretary*

Board of Registration in Medicine,
State House, Boston.

HEALTH-CONTEST QUESTIONNAIRES

To the Editor The Boston Health Department has recently asked Boston physicians to furnish certain statistical data for use in a health contest conducted by the United States Chamber of Commerce.

The questions to be answered concern chiefly the prophylactic immunizations carried out on children and the obstetrical and genitourinary cases treated privately by individual physicians during the year 1937. The letter accompanying the questionnaire explains that such information will presumably show how well we as a class meet this modern problem of health conservation.

No one will question the wisdom and desirability of such a campaign, but one must wonder at the naïveté with which our health authorities expect such information without having previously given notice that such statistics would be called for.

To quote a very reputable physician who is also a high official in one of our medical societies: While we may keep good records of our individual cases, one rarely keeps separate any record of the number of inoculations or the number of pneumonias. We shall be able to wade through it somehow, but one feels that the information so obtained must of necessity be either grossly exaggerated or just as badly underestimated, according to the mood or memory of the individual supplying the data. By no means can it be called a fair estimate of the actual amount of preventive work done by our private practitioners.

If our health authorities are really interested in such statistics, they should furnish us with the proper charts so that we can keep constant records of such work. In this way desired information could easily be obtained at any time, and it would be both genuine and valuable. The figures so obtained would also show the staggering amount of work really done, and the oft-repeated statement that private practitioners are not interested in preventive medicine would prove to be nonexistent.

RUBIN GURALNICK, M.D.

256 Bennington Street,
East Boston, Mass.

RECENT DEATHS

REARDON—TIMOTHY J. REARDON, M.D., of 76 Commonwealth Avenue, Boston, died February 17. He was in his sixty-sixth year.

Born in Boston, he received his early education in the local schools, later earning his way through Harvard Medical School from which he received his degree in 1894. He spent the next three years at the University of Vienna, following which he spent two years at the Université de Paris and one year in London hospitals.

On his return to Boston, he specialized in diseases of the nose and throat. At one time a trustee of the Boston City Hospital, he was also staff physician at the Carney Hospital and the Boston School for the Deaf at Randolph.

Dr. Reardon was a fellow of the Massachusetts Medical

Society and the American Medical Association. He was a member of the New England Otological and Laryngological Society and the Boston Medical Library.

His two sisters, the Misses Nellie and Mary Reardon, survive him.

HARE—E. TRENN HARE, M.D., of 225 High Street, Holbrook, died February 17. He was in his thirty-sixth year.

A native of Gilbertville, he received his degree from the University of Vermont College of Medicine. He served internships at the Eye and Ear Hospital, Brooklyn, and the Roosevelt Hospital, New York City, after which he opened an office, specializing in eye, ear, nose and throat diseases.

Dr. Hare was a fellow of the Massachusetts Medical Society and a member of the American Medical Association.

MOLLIKA—ZACHARY A. MOLLIKA, M.D., of 48 Prentiss Lane, Belmont, died at sea, January 31. He was in his fiftieth year.

Dr. Mollica received his degree in 1912 from the Medical College of the State of South Carolina. Following his graduation he specialized in surgery.

He was a fellow of the American Medical Association and the Massachusetts Medical Society.

His widow survives him.

NOTICES

BOSTON DISPENSARY

25 Bennet Street, Boston
Lecture Hall, Second Floor, 9-10 a. m.

The Boston Dispensary will hold its next medical conference on Friday morning, February 25.

Dr. John G. Gibson, Jr., will speak on 'Clinical Studies of Blood Volume.' He was invited to address the meeting in place of the previously announced speaker, Dr. Bernard Jacobson.

MEDICAL CONFERENCE PROGRAM, MARCH, 1938

Tuesday, March 1—Injuries to the Epiphyses. Dr. John D. Adams

Wednesday, March 2—Hospital Case Presentation. Dr. S. J. Thannhauser

Thursday, March 3—Social Instability and the Doctor. Prof. Elton Mayo

Friday, March 4—Mumps. Dr. Conrad Wesselhoeft.

Saturday, March 5—Hospital Case Presentation. Dr. S. J. Thannhauser

Tuesday, March 8—Phlebitis. Dr. Edward A. Edwards

Wednesday, March 9—Hospital Case Presentation. Dr. S. J. Thannhauser

Thursday, March 10—Social Service Case Presentation. Mrs. H. B. Hooker and Miss E. Grundy

Friday, March 11—Some of the Newer Aspects of Colapse Treatment of Pulmonary Tuberculosis. Dr. Richard H. Overholt.

Saturday, March 12—Hospital Case Presentation. Dr. S. J. Thannhauser

Tuesday, March 15—Clinicopathological Conference. Dr. R. C. Wadsworth.

Wednesday, March 16—Hospital Case Presentation. Dr. S. J. Thannhauser

Thursday, March 17—Allergic Manifestations in Certain Dermatoses. Their Recognition and Treatment. Dr. Francis M. Thurmon.

assistant in pediatrics, Henry C Marble, of Boston, assistant in industrial hygiene, William F Dolan, of Arlington, assistant in industrial hygiene, George W Morse, of Brookline, assistant in industrial hygiene, and Philip C Trexler, of South Bend, Indiana, research fellow in bacteriology

CORRESPONDENCE

SERUM TREATMENT OF PNEUMONIA

To the Editor The success of the program being carried on by the Massachusetts Department of Public Health to decrease deaths from pneumonia by use of specific serums is dependent upon encouraging physicians to make use of the facilities at their disposal. One important phase of this matter is making laboratory facilities easily available. A sufficient number of hospitals are co-operating in this plan so that typings can now be done in every part of the State. Many physicians have been making use of the laboratory facilities for typing pneumococci from sputum.

The facilities for isolating pneumococci from the blood stream, on the other hand, have not been so widespread, and such service has been available only in larger hospitals. This shortcoming is being remedied as rapidly as possible. A number of additional laboratories are adding this test to those offered to physicians. The outfits for collecting blood samples can be obtained at the same time as the therapeutic serum. They should be returned to the same laboratory by messenger, since they do not conform to postal regulations and consequently cannot be mailed.

An additional handicap has been that in parts of the State some distance removed from the Bacteriological Laboratory at the State House, patients who have been unable to pay for laboratory work have been dependent upon the generosity of the local hospitals for typing service. A fund has been set up to be used in paying approved laboratories for tests done on such patients. In this way, the burden will be removed from the local laboratories, and physicians will feel much freer to have sputum typings and blood cultures done on indigent patients.

In order to safeguard the expenditures from this fund, regulations in regard to payments from it have been set up by the department. These are as follows:

Payments will be made for typing pneumococci from sputum and blood cultures from persons having, or suspected of having, pneumonia under the following conditions:

- 1 If the tests are done for patients outside the hospital in which the typing laboratory is situated
- 2 If the laboratory requesting payment is approved by this department for doing such tests, if the tests are performed or checked by an approved technician, and if the laboratory certifies that payment for the tests has not been made.
- 3 If the physician when submitting the specimen certifies over his signature that the payment of the charges would be an undue hardship on the patient.
- 4 If the number of examinations on a single patient is reasonable and satisfactory explanation for repeated tests accompanies the bill.

5 If the pneumococcus typing has covered all the types for which typing serum is provided by the department.

6 If the bill is submitted for approval by the 10th of the next succeeding month after the tests are performed.

Item four should not be interpreted as limiting the number of tests to one sputum and one blood culture. Additional sputum samples should be examined on every patient who does not respond promptly to serum therapy. At least one blood culture should be done on every patient. In addition, further specimens should be obtained from those who have shown a previously positive blood culture, or from patients in whom the temperature fails to drop after serum therapy.

HENRY D CHADWICK, M.D.,
Commissioner of Public Health

State House,
Boston.

SUPPORT OF LEGISLATIVE COMMITTEE

To the Editor We now have as chairman of the Committee on State and National Legislation of the Massachusetts Medical Society, Dr Charles Lund, of Boston, who is putting his heart and soul into the work at hand. We in Hampden County have felt that the legislative program cannot be entirely handled at the State House. With this thought in mind, on Saturday night, February 12, the district society invited the senators and representatives from this district to a steak dinner at the Highland Hotel. Along with the legislators we invited our local members who are active in civic and political life, in some cases the family doctor of this or that legislator, and outstanding men whose presence would lend dignity and weight to our cause. Our local president, Dr Allen G Rice, presided, and Dr Lund made a trip from Boston to explain our position on pending bills in which we are interested.

A feeling of respect and confidence was present throughout the evening. The legislators asked many questions and showed an intelligent interest in solving problems as presented for the best interest of the State of Massachusetts. On this ground we are never fearful of the result.

Dr Lund impressed the legislators and the doctors with his sincerity, his intelligence and his fair mindedness, and I am writing this letter to the *Journal* so that the other district societies throughout the State may consider making an effort comparable to ours. We believe that the legislators should understand health problems, and realize that the doctors are really interested in what their elected representatives do. Our opponents are ever on the alert, and we cannot expect legislators to believe very much in the plea of physicians who are strangers to them, when the doctors in their own districts do not take the time to interest themselves in these health measures.

We should very much like to see every county society doing its bit toward a united front. There is no reason why a few should have to do the work for the many.

W A R CHAPIN, M.D.,
Legislative Chairman
Hampden County Medical Society

121 Chestnut Street,
Springfield, Massachusetts.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, FEBRUARY 28

MONDAY FEBRUARY 28

* 15 p. m. New England Heart Association New England Pediatric Hospital

TUESDAY MARCH 1

9-10 a. m. Boston Dispensary Injuries of the Epiphyses. Dr. J. N. Adams

10 a. m. 12:30 p. m. Tumor clinic Boston Dispensary

11:30 a. m. Carney Hospital John T. Bottomley Society Outpatient department

8:30 p. m. Greater Boston Medical Society Beth Israel Hospital auditorium

WEDNESDAY MARCH 2

9-10 a. m. Boston Dispensary Hospital case presentation Dr. S. J. Thannhauser

1 p. m. Clinicopathological conference Children's Hospital Amphitheater

THURSDAY MARCH 3

8:30-9:30 a. m. Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital

*9-10 a. m. Boston Dispensary Social Instability and the Doctor Prof. Elton Mayo

4 p. m. George Washington Gay lecture Tufts College Medical School

5 p. m. Faulkner Hospital clinicopathological conference

FRIDAY MARCH 4

*9-10 a. m. Boston Dispensary Mumps Dr. Conrad Wesselschoft

10 a. m. 12:30 p. m. Tumor clinic Boston Dispensary

12 m. Clinical meeting of the Children's Medical Service Massachusetts General Hospital Ether Dome

SATURDAY MARCH 5

*9-10 a. m. Boston Dispensary Hospital case presentation Dr. S. J. Thannhauser

10 a. m. 12 m. Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr. Henry A. Christian

SUNDAY MARCH 6

4 p. m. Illustrated public health lecture, Faulkner Hospital auditorium, Chest Operations in the Treatment of Tuberculosis Dr. Harlan F. Newton

4 p. m. Free public lecture, Harvard Medical School amphitheater of Building D Heart Disease Dr. Herman Blumgart

4 p. m. Free public lecture, Beth Israel Hospital Boston in conjunction with the Women's Auxiliary What Can Be Done in Arthritis Dr. Armin Klein

*Open to the medical profession

BRISTOL SOUTH

MAY 5—5 p. m. New Bedford

ESSEX SOUTH

MARCH 2—Lynn Hospital Clinic at 5 p. m. Dinner at 7 p. m. Speaker and subject to be announced

APRIL 6—Gloucester Hospital Gloucester Clinic at 5 p. m. Dinner at 7 p. m. Speaker and subject to be announced

MAY 5—Censors meet at Salem Hospital 3:30 p. m.

MAY 11—Annual meeting Salem Country Club Peabody Dinner at 7 p. m. Speaker and subject to be announced

FRANKLIN

Meetings will be held at the Franklin County Hospital Greenfield, at 11 a. m. the second Tuesdays of March and May

HAMPTON

Meetings will be held on the fourth Tuesday in April and July

MIDDLESEX EAST

Meetings will be held at the Bear Hill Golf Club, Stoneham at 12:15 p. m. on March 16 and May 11

MIDDLESEX NORTH

Meeting will be held at the Vesper Country Club Lowell on April 27

NORFOLK DISTRICT

MARCH 29—Hotel Kenmore 8:15 p. m. Subject to be announced but to be related to diseases of the kidney Dr. Albert A. Horner

MAY—Annual meeting

The censors meet on the first Thursdays of May and November in each year

NORFOLK SOUTH

Meetings held at 12 noon

MARCH 3—Norfolk County Hospital South Braintree

APRIL 7—At the Quincy City Hospital

MAY 5—Annual meeting

PLYMOUTH

Meetings will be held at 11 a. m. on March 17 April 21 May 19 and July 21

SUFFOLK

MARCH 15—Joint meeting with Boston Obstetrical Society

WORCESTER

At the following meetings, except the annual meeting dinner will be at 6:15 to be followed by business session and scientific program.

MARCH 9—Memorial Hospital Worcester

APRIL 13—Habermann Hospital Worcester

MAY 11—Afternoon and evening annual meeting Place and schedule of program to be announced.

BOOK REVIEWS

The Cerebrospinal Fluid H. Houston Merritt and Frank Fremont-Smith. 333 pp. Philadelphia and London W. B. Saunders Company, 1937 \$5.00

Previous books on the cerebrospinal fluid, as pointed out by Dr. J. B. Ayer in the foreword, are now outmoded, for they were written too early in the history of clinical investigation of the spinal fluid to be able to present accurate correlation between laboratory and clinical findings. This fine book, which originally was started in the Spinal-Fluid Laboratory at the Massachusetts General Hospital and later continued in the laboratory of the Neurological Unit of the Boston City Hospital, is based on the examination of approximately 21,000 spinal fluids from patients whose diagnoses have been verified. The volume consists of a brief historical introduction, excellent chap-

Friday, March 18—Certain Clinical Features of the Natural History of Rheumatic Fever and Heart Disease. Dr T Duckett Jones

Saturday, March 19—Hospital Case Presentation. Dr S J Thannhauser

Tuesday, March 22—X-ray Demonstration. Dr Alice Ettinger

Wednesday, March 23—Hospital Case Presentation. Dr S J Thannhauser

Thursday, March 24—Some Practical Considerations of Muscle Imbalance. Dr Joseph J Skirball.

Friday, March 25—Some Aspects of Pneumonia Therapy. Dr Maxwell Finland

Saturday, March 26—Hospital Case Presentation. Dr S. J Thannhauser

Tuesday, March 29—A Clinical Evaluation of the Blood Sedimentation Rate as a Routine Diagnostic Procedure. Dr Elbert B Agnor

Wednesday, March 30—Hospital Case Presentation. Dr S J Thannhauser

Thursday, March 31—Interesting Clinical Problems from the District Service. Dr Isadore Olef.

RADIO BROADCASTS

The sixth group of weekly broadcasts sponsored by the American Medical Association and the National Broadcasting Company concern public health. These dramatized health messages are intended to furnish supplementary material for health teaching in junior and senior high schools and are broadcast every Wednesday from 2 00 to 2 30 p m over the Red Network. The dates and subjects are as follows:

March 2—Water, Waste and Sanitation. Importance of community control of water supplies, sewage disposal and general sanitary matters.

March 9—Protecting Perishable Foods. What the community can and must do to protect fresh foods such as fish, fruits, vegetables, meats, bakery goods.

March 16—Keeping Books on Health. The meaning and the importance of vital statistics, contagious-disease reporting and community-health records.

March 23—Catching Disease from Animals. Rabbit fever, rabies, undulant fever and similar infections, and what can be done about them.

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high-voltage x-ray.

Physicians are welcome to visit this clinic and bring a patient to the clinic for diagnosis.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the New England Deaconess Hospital, on Monday, February 28, at 8 15 p m.

PROGRAM

Prognosis of Adult Women with Mitral Stenosis. Dr Burton E. Hamilton.

The Heart in Postoperative Deaths. Dr Shields Warren.

A Case of Congenital Heart Block. Dr William B Stevens and Dr F Gorham Brigham.

Heart Noises. Case report. Dr Frank N Allan.

Cardiovascular Disease in Diabetes. Dr Howard Root.

Selection and Operative Treatment of Hypertension. Dr Elmer C Bartels.

Congestive Failure on Using Digitalis. Dr Lewis Hurxthal.

Interested physicians and medical students are invited to attend.

JAMES M. FAULKNER, M.D., *Secretary*

NEW ENGLAND PEDIATRIC SOCIETY

The regular meeting of the New England Pediatric Society will be held at the Massachusetts General Hospital, on Friday, February 25. The clinical program will begin at 4 30 p m., and the evening meeting at 7 45. Dr Joseph C Aub will speak on 'Endocrine Disorders of Childhood.'

CARNEY HOSPITAL

The John T. Bottomley Society of the Carney Hospital Outpatient Department will hold its regular monthly meeting on Tuesday, March 1, at 11 30 a. m. Dr William E. Browne will speak on 'Important Bony Land Marks and Surface Markings of Various Anatomical Spaces.'

WILLIAM J. MACDONALD, M.D., *Secretary*

THE FAULKNER HOSPITAL

The usual clinicopathological conference will be held at the Faulkner Hospital for its staff and any other interested members of the medical profession on Thursday, March 3, at 5 00 p m.

There will be a discussion of cases by Dr Marshall K. Bartlett and Dr Maurice B. Strauss.

JOHN B. HAZARD, M.D., *Secretary*

BOSTON UNIVERSITY MEDICAL SOCIETY

The next meeting of the Boston University Medical Society will be held in the Evans Memorial Auditorium, 78 East Concord Street, Boston, on Monday, March 7, at 12 o'clock noon.

Dr Morris Fishbein, editor of the *Journal of the American Medical Association* will speak on 'Quacks and Quackery.'

Medical students, nurses and physicians are cordially invited to attend.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, March 8, at 8 15 p m.

PROGRAM

Presentation of Cases.

Exchanges between Cells and Interstitial Fluid. Dr John P. Peters, New Haven, Connecticut.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING
MONDAY, FEBRUARY 28

MONDAY FEBRUARY 28

8:15 p. m. New England Heart Association. New England Deaconess Hospital

PLYMOUTH

Meetings will be held at 11 a. m. on March 17, April 21, May 19 and July 21.

SUFFOLK

MARCH 15—Joint meeting with Boston Obstetrical Society.

WORCESTER

At the following meetings, except the annual meeting, dinner will be at 6:15 to be followed by business session and scientific program.

MARCH 9—Memorial Hospital, Worcester.

APRIL 13—Hahemann Hospital, Worcester.

MAY 11—Afternoon and evening annual meeting. Place and schedule of program to be announced.

BOOK REVIEWS

The Cerebrospinal Fluid. H. Houston Merritt and Frank Fremont-Smith. 333 pp. Philadelphia and London W. B. Saunders Company, 1937. \$5.00.

Previous books on the cerebrospinal fluid, as pointed out by Dr. J. B. Ayer in the foreword, are now outmoded, for they were written too early in the history of clinical investigation or the spinal fluid to be able to present accurate correlation between laboratory and clinical findings. This fine book, which originally was started in the Spinal-Fluid Laboratory at the Massachusetts General Hospital and later continued in the laboratory of the Neurological Unit of the Boston City Hospital, is based on the examination of approximately 21,000 spinal fluids from patients whose diagnoses have been verified. The volume consists of a brief historical introduction, excellent chap-

ters on the anatomy and physiology of the cerebrospinal fluid, its chemistry and pathologic physiology, the technic of lumbar puncture, the cerebrospinal fluid syndromes and methods of laboratory examination, and an extensive bibliography and index. The volume is illustrated by numerous charts and tables. The subject is covered very completely, and the volume will become an essential part of the equipment of any first-class laboratory or hospital, as well as an important addition to the library of all medical practitioners.

In turning over the pages, it is interesting to note that the authors hold the view, now almost universally accepted, that the choroid plexus is the site of origin of the spinal fluid, that its exit from the ventricles is through the foramina of Luschka, and that the supposed foramen in the midline of the fourth ventricle, as described by Magendie, is probably not a functional opening, and that the evidence favors Mestrezats theory that the cerebrospinal fluid is a dialysate. The function of the spinal fluid is probably a mechanical one, as described by Magendie in 1842. Puzzling points, which have often bothered practitioners, are explained. It has been erroneously claimed that the irritation of a simple lumbar puncture may cause meningeal reaction, which is manifested by a pleocytosis at a subsequent puncture. The authors found no evidence of such a reaction. They have devised a technic by which bloody fluid obtained at lumbar puncture as the result of imperfect withdrawal may be evaluated so that the actual white-cell count and protein may be estimated. They have not found any treatment efficient in post lumbar puncture headache, except the postural one of keeping the patient in a horizontal position. They point out that the colloidal gold reaction is no longer thought to be diagnostic of any particular disease of the central nervous system, but is simply an indication of an abnormality of the protein content of the fluid. For this reason they have wisely discarded the prejudicial terms 'paretic', 'syphilitic' and 'meningitic' curves and have replaced them by the terms 'first zone', 'midzone' and 'end zone' curves.

The value of this book lies in the accumulated and carefully analyzed data from a large series of cerebrospinal fluids, and all the syndromes as seen in various diseases—material that has never been adequately presented to the medical profession before. Except for the reduction in the size of some of the charts, which has resulted in making them difficult to read, the reviewer has no criticism of this outstanding publication.

Not So Long Ago. A chronicle of medicine and doctors in colonial Philadelphia. Cecil K. Drinker. 183 pp. New York: Oxford University Press, 1937. \$3.50.

In Philadelphia, back in 1758, the young matron Elizabeth Drinker began keeping a diary, and a diarist she continued to be almost to the end of her days in 1807. Now comes her great great-grandson to comb her journals for matters of medical interest and to make those matters into a book.

It was a rich lode which he struck. Elizabeth Drinker had nine children and twenty-five grandchildren, and the medical experiences of this numerous progeny and those of her husband, her servants and her neighbors were among her most pressing concerns all her life. The Drinkers were well-to-do folk and in her various and frequent exigencies she could command the best medical advice the times had to offer. Benjamin Rush, William Shippen, Adam Kuhn, Philip Syng Physick and John Bard—prominent names all in American medical history—appear repeatedly in her pages.

Yet these men, able, hard working and conscientious

as they were, could do but little (one sees now) to lessen the medical hazards that then beset life. Strong in system and theory they really possessed but a minimum of fundamental knowledge." Even in Philadelphia, the largest and perhaps richest city in the colonies, there was no sanitation, hospital facilities were vastly inadequate, and what with typhoid, smallpox, dysenteries, yellow fever and other epidemic diseases there was a heavy mortality among the youthful. Of Elizabeth Drinker's nine children only five lived to maturity and one of these was for years in a precarious state from tuberculosis.

Very wisely Dr. Drinker groups his quotations according to subject rather than chronology. Thus one finds chapters on childbearing in 1790, on the tuberculosis of William Drinker, on smallpox and the fevers, on yellow fever in Philadelphia, and on medical practice in 1800. His own part in the exegesis is to supply the backgrounds and the broad settings, to introduce the people, to furnish the continuity, and on occasion judiciously to comment. But particular events are presented always through the eyes of his ancestors.

Viewed as a whole the book is a notable contribution to social as well as to medical history. It leaves one with a vivid sense of the life of a period, of what people must needs then endure of fleshly ailments, and of what vast strides medicine has taken since that time—after all not so long ago. No one who is interested in the development of American medicine can afford to pass it by. Indeed, one might suppose that the layman would enjoy it almost as much as the physician. Dr. Drinker is to be heartily congratulated on his achievement.

Modern Treatment in General Practice Volume 3. Edited by Cecil P. G. Wakeley. 436 pp. Baltimore: William Wood & Company, 1937. \$4.00.

This is the third volume of selected papers reprinted from current issues of *The Medical Press and Circular* of London, England. The subjects are chosen with particular reference to the needs of general practitioners in that they deal primarily with diagnosis and treatment. They have been written by surgeons and physicians representing a fair cross section of skilled British practice.

There are fifty-one chapters, each one devoted to a special subject. Of this number six are allotted to cancer in various situations, eight to different problems in the realm of psychiatry, psychology, behaviorism and several organic, central nervous-system diseases, such as sclerosis (disseminated), general paresis, epilepsy and cerebral syphilis. For the other subjects there are excellent discussions of intestinal obstruction, colitis, anal fistula, gastric and duodenal ulcers, esophageal obstruction, congenital dislocation of the hip, infantile paralysis, injuries to the wrist, harelip, injection treatment of varicose veins, industrial injuries to the hand and foot, and fractures of the pelvis and complications, treatment of edema, chorea, cirrhosis of the liver, cardiac failure, cholecystitis, acute rheumatism, prostatic enlargement, osteoarthritis, essential hypertension, hyperchromic anemia, chronic bronchitis and asthma, ophthalmic emergencies, traumatic abdominal emergencies and pulmonary suppuration, value of blood examinations to the general practitioner, tumors of pituitary gland, treatment of ringworm of the foot, tuberculosis of the skin, acute pyelitis, histidine treatment of peptic ulcer, and treatment of angina pectoris, the modern treatment of dysentery and dietetic essentials for the general practitioner. The above is nothing more than the table of contents. It would be impossible to give space to a detailed review of each article, but suffice it to say that they are written uniformly well and present modern English opinion in a clear-cut, practical manner.

NUMBER 9

LATE RESULTS FOLLOWING THE USE OF INSULIN IN ONE HUNDRED CASES OF MALNUTRITION

HARRY BLOTNER, M.D.*

BOSTON

THE use of insulin in producing a rapid gain in weight in patients with nondiabetic malnutrition has been well established¹. Since its introduction for this purpose an extensive literature on the subject has been gathered, in general immediate improvement with this form of therapy has been obtained. Practically nothing, however, has been written concerning the course of these patients after the discontinuance of insulin. It has seemed of value to follow a group of these patients for a considerable period, and to observe what changes had taken place in the weight, the general condition and the carbohydrate tolerance after discontinuance. This paper reports a follow-up study of 100 patients with nondiabetic malnutrition who had gained weight with insulin treatment, and who were observed for from one to six years after its cessation.

CLINICAL MATERIAL

Fifty-four women and 46 men were studied. All were ambulatory and normal physically except for from moderate to severe malnutrition. Their ages ranged from eighteen to seventy-one. Practically all of them had been underweight for years, and their best weights in most instances were no more than they had been when insulin was started. All had tried to gain weight by one method or another, but without success. The majority were constitutionally asthenic and were nervous, apprehensive, easily fatigued, lacking in energy and dyspeptic, some, however, were of the thin type who ate and felt well. The urine in all patients was normal, and the blood-sugar concentration, as determined in many instances before starting insulin therapy, was within normal limits.

The patients ordinarily injected 10 units of insulin three times a day about twenty minutes before meals. A few took insulin twice a day, and in rare instances the dose was increased to 20 units two or three times a day. The insulin was usually

taken for from one to three months, the shortest period being two weeks and the longest seven months. A liberal diet was advised.

IMMEDIATE RESULTS WITH INSULIN

The immediate effects of insulin therapy were a gain in weight and an improvement in appetite, which varied in individual patients. In most cases the gain was from 3 to 4 lb per week for the first two or three weeks, it became less marked as time progressed. Finally, the weight remained constant regardless of the administration of insulin. The greatest increase in any patient in one week was 9 lb. Most of the group noted an improved general and mental condition, an increase in strength and efficiency and a better gastrointestinal function. The gain in weight appeared to be due to an actual increase in the deposit of fat and not to edema. This was suggested by the measuring of the fluid intake and output in 11 patients.

Table 1 *Gain in Weight in 100 Thin Patients during Insulin Therapy*

NO. OF CASES	PERIOD OF TREATMENT	GAIN IN WEIGHT lb	AVERAGE GAIN IN WEIGHT lb
6	2 wk.	3-8	6
13	3	5-16	8
22	4-5	4-22	10
14	6-7	5-24	14
10	2 mo.	9-19	15
16	2½	8-19	14
15	3-4	8-31	15
4	6-7	16-25	20

during and after insulin therapy, the relation between them being practically unchanged. In 1 case during insulin treatment² repeated biopsies of the abdominal wall showed a remarkable increase in the size of fat cells and in the depth of the subcutaneous fat. The weight gained during various periods of insulin therapy is given in Table 1.

WEIGHT AFTER OMITTING INSULIN

The weight of patients in this group was noted during periods which ranged from one to six years after the cessation of insulin treatment. The pa-

tients were observed as follows 26 for one year, 12 for two years, 19 for three years and 43 for from four to six years The results are given in Table 2

Table 2 *Duration of Added Weight in 100 Patients after Discontinuing Insulin*

NO OF CASES	FOLLOW UP PERIOD	NO OF CASES RETAINING ALL GAINED WEIGHT	NO OF CASES LOSING WEIGHT
26	1 yr	17	6 lost all within 1 year 3 lost most of gain in 1 year
12	2	5	3 lost all in a few months 4 held weight 1 yr then lost gradually
19	3	11	4 lost all in 6 mo 4 kept weight 1 yr then lost gradually
43	4-6	26	10 held weight from 1 to 2 yr then lost gradually 7 retained about half of added weight

Of the 26 patients observed for one year after discontinuing insulin, 17 retained the added weight, 6 lost it all and 3 maintained less than half the gained weight Of the 12 patients followed for two years, 5 maintained the gain, 3 lost the added weight shortly after discontinuing insulin and 4 held the weight for approximately a year and then lost it gradually during the subsequent year Of the 19 patients followed for three years, 11 maintained the gained weight, 4 lost it all within six months and 4 kept the weight for approximately one year and then lost it slowly over varying periods of time Of the 43 patients followed for from four to six years, 26 held the added weight, 10 maintained the gain for from one to two years and then lost during varying intervals of time and 7 retained about one half the gained weight

The majority of the patients have maintained the increased weight during the various follow-up periods and have felt better because of it These results are in striking contrast to those obtained by Nichol,³ who in following 42 patients who gained weight with insulin found that 31 maintained their gain for six months or less, and only 4 kept the weight for three or four years The chief cause for these different results may possibly be the difference between the climate of southern Florida and that of this part of the country Also, some of Nichol's patients had organic disease

It was difficult to predict which patients would retain and which would lose the added weight In general, those who gained the most weight were the most likely to retain it This was not an invariable rule, because some of those who made lesser gains maintained the weight, whereas others who made greater gains lost it all Some patients continued to feel better in spite of a loss in weight after discontinuing insulin

The chief causes for the loss of weight after cessation of insulin treatment were unhappy love affairs, poor economic conditions and disagreeable occupations Other losses were due to acute in-

fections, "nervousness" and serious family illness. Some patients who were students lost because of irregular intake of food and worry over examinations

The best results obtained with insulin may be illustrated by citing briefly the case of a doctor aged sixty-three who was having marital difficulty He became very nervous, depressed and weak, was unable to eat and lost 35 lb in about two months He took 10 units of insulin three times a day before meals for five weeks and put on 22 lb, and began to improve generally in spite of persistent marital trouble During the subsequent year he gained an additional 9 lb At the end of two years his weight was constant, he felt much better, and said that if it were not for insulin he would not be alive

Ten of the patients, listed as maintaining their added weight, continued to gain after discontinuing insulin The results of these cases are given in Table 3 Apparently there was very little danger of obesity's developing after discontinuing insulin Although 4 patients became from 10 to 35 lb overweight for their age, height and sex, one of them became definitely obese

Table 3 *Record of Ten Patients Who Gained after Discontinuing Insulin*

NO OF CASES	WEIGHT GAINED ON INSULIN	WEIGHT GAINED AFTER STOPPING INSULIN	PERIOD OF GAIN	COMMENT ON WEIGHT
	lb	lb		
2	10-15	5	1/2 3 yr	Gradual gain
3	6-12	6-7	3-4	Same for past 6 mo
2	11-31	13-16	4-5	Constant for last year
2	22-24	9-18	1	Same for past 1 1/2 yr
1	15	54	4	Gradual gain.

CARBOHYDRATE TOLERANCE

In a previous study I made some observations⁴ on the sugar tolerance in 25 thin patients who gained weight with insulin, and found a temporary decrease in the glucose tolerance in certain cases during the period of insulin treatment However, the sugar tolerance returned to normal shortly after the insulin was discontinued Later Odin⁵ made similar observations in subjecting habitually thin patients to fattening treatment with insulin, he also noted in certain cases a decreased carbohydrate tolerance, attended by an increased blood sugar curve and excretion of sugar in the urine during the dextrose-tolerance test Recently Dusik,⁶ working with Sakel on the insulin-shock treatment of schizophrenia, informed me that glycosuria appeared before breakfast in some cases on the morning following insulin treatment Occasionally a high blood sugar occurred in the afternoon after glucose had been administered for the insulin shock Shortly after treatment was stopped the blood sugar and urine became normal

It seemed important to observe more particularly the effect of insulin on the carbohydrate metabolism in a large group of such persons, and to determine whether any abnormal changes developed after a considerable period of time had elapsed after discontinuing insulin. This work was carried out by testing the urine and blood for sugar in fasting and non fasting specimens at varying intervals of time during the periods of observation, which ranged from one to six years after the cessation of insulin treatment.

The urine was examined in most of the 100 patients seen a year after discontinuing insulin, and also in a majority of those followed at the end of two or three years. In no case was there any glycosuria. The blood sugar also was determined in many cases at the end of one year and in an occasional case after two or three years. These values also were normal, and the figures are therefore not given. Finally, nearly all the patients followed for from four to six years had urine examinations, while in 11 the blood sugar was determined at the end of the follow-up period. These results, too, were perfectly normal. In no case did albuminuria develop as the result of insulin.

INSULIN HYPERSENSITIVENESS

Local skin reactions appeared at the site of insulin injections in 31 per cent of the cases. These were characterized by a somewhat indurated and slightly tender lump with a superficial erythema from 3 to 5 cm in diameter. This hypersensitivity ordinarily started from seven to ten days after the beginning of insulin treatment, and disappeared after varying intervals of time, usually in several weeks. In 3 cases there was a mild urticaria, which necessitated the stopping of insulin in 1 patient who was unusually sensitive to a number of proteins.

One patient was of unusual interest in this relation. She took insulin five and a half years ago for three months without having insulin sensitivity. During the intervening period she lost the gained weight and resumed insulin seven months ago. After two weeks of insulin treatment she developed giant urticaria from the top of her head to the tip of her toes about a half hour after taking an injection of insulin. The insulin was omitted for several days, and after resuming it the hives reappeared. Apparently this patient developed a sensitivity to insulin.

DISCUSSION

Most doctors have encountered extremely thin nondiabetic patients in whom there had been considerable difficulty in improving the state of nutrition with such measures as diet, tonics, rest and vacations. Insulin has become a very useful thera-

peutic adjunct in the management of such cases where the ordinary methods have been unsuccessful. Along with the gain in weight, insulin improved the nervous state, the general condition and the vigor of many patients. It is of special interest that most of the patients have maintained the added weight and the better general condition for as long as six years after the cessation of insulin treatment. It appeared quite likely that a number of those patients who lost the gained weight would have retained all or part of it had it not been for the various complicating factors which arose during the follow-up periods. Insulin was of temporary benefit, at least in those who did not retain the weight permanently.

In estimating the value of any therapeutic agent it is important to ascertain whether any harmful temporary or permanent effects may result from it. In this connection, the only point requiring mention is the temporary decrease in the sugar tolerance which was found in some cases during the period of insulin administration. This was apparently of no practical importance, since the tolerance returned to normal in a short while. In order to prove that the impaired carbohydrate tolerance was not permanent, tests for sugar in the blood and urine were made in the cases examined at intervals up to six years after the discontinuance of insulin, all were found to be normal.

SUMMARY

A study is presented of the late results obtained in 100 thin individuals, without organic disease, who gained weight with insulin and who were observed for from one to six years after the cessation of insulin therapy.

The immediate effects of insulin treatment were a gain in weight, a better appetite and an improvement in general condition, all these varied according to the individual patient.

The majority of the patients maintained the added weight and the improved general condition for as long as six years after discontinuing insulin, and a few continued to gain, but one became definitely obese. Insulin induced at least a temporary improvement in those who did not retain the weight. Various complicating factors were adequate causes for the loss of the gained weight in a number of cases.

In some patients there was a decrease in the sugar tolerance during the period of insulin treatment, but this returned to normal shortly after discontinuing insulin. There was no permanent impairment of the carbohydrate tolerance.

Insulin has become a valuable therapeutic adjunct in the management of certain patients with nondiabetic malnutrition who have had difficulty

in gaining with the ordinary methods of treatment

PERNICIOUS ANEMIA DUE TO ENTEROENTEROSTOMY

Report of a Case Cured by Reoperation

WYMAN RICHARDSON, M.D.*

BOSTON

FABER in 1897 reported cases of pernicious anemia apparently due to chronic obstruction of the small bowel. Meulengracht¹ collected 22 such cases. Not all these are reported in detail, but several had fecal fistulas. Most of the cases had obstruction in the lower ileum with dilatation above, and the majority had achlorhydria. One of Meulengracht's patients was cured by operation, and the only one treated with liver was entirely relieved by its use.

In the case reported by Little, Zervas and Trusler,² lateral bowel anastomosis was performed twice, pernicious anemia appeared several years later. The anastomosis was undone and 24 cm. of jejunum was excised. Gastric analysis showed the presence of free hydrochloric acid. The patient made a prompt response to liver extract, but had a recurrence of anemia when the liver was omitted.

Strauss³ mentions 2 cases of pernicious anemia following secondary short-circuiting operations after appendectomy, one in a boy eight years old. Taylor⁴ has reported a case with intestinal diverticulosis, pernicious anemia and bilateral supraceliac apoplexy. Sturgis⁵ mentions a case of pernicious anemia, apparently dependent upon an anastomosis of the jejunum to the transverse colon, which was relieved by the administration of liver extract intramuscularly. Butt and Watkins,⁶ like other observers, have found blood pictures suggesting pernicious anemia in a variety of conditions in which there is severe disorder of the lower intestinal tract, such as regional ileitis, carcinoma of the ileum or cecum, diverticulosis of the colon and multiple fecal fistulas of the small intestine.

Nutritional disturbances after such operations are fairly common, but very few (Meulengracht,¹ Case 2) in which complete relief has been obtained

by reoperation have been reported. It seems worthwhile, therefore, to report another case of pernicious anemia apparently cured by restoring to normal a short-circuited bowel.

CASE REPORT

A 30-year-old man, an instructor in a university, was first seen in February, 1933. In June, 1930, he had been operated on for acute appendicitis. One month later, for symptoms not clearly defined by the patient, he was again operated upon, an enteroenterostomy was done. It was said that the lower 180 cm. of ileum was short-circuited.

Following this operation, the patient developed a severe diarrhea and regained strength very slowly. In the spring of 1932 he was given liver extract by mouth and felt well in the summer, but this treatment was not continued. The following autumn he became anemic, felt tired and weak, and suffered from diarrhea, with three or four loose, light-colored stools daily. There was no soreness of the tongue, and only slight numbness of the fingers of the right hand.

The family history was unimportant. There was no familial premature graying of the hair, but rather a tendency to baldness; there was no familial jaundice or anemia.

The only important illness was rheumatic fever at the age of eight years. There had been no weight loss and no dietary idiosyncrasies.

At physical examination in February, 1933, the sclerae were definitely icteric, the heart was slightly enlarged, with definite but slight mitral stenotic and aortic regurgitant murmurs. The blood pressure was 120/50. The tongue appeared normal. Neither the liver nor spleen could be felt. The knee jerks were normal. Vibration sense was normal over the tibiae. The urine was highly colored but contained no bile. The red-blood-cell count was 2,900,000. The hemoglobin was 60 per cent (Tallqvist) and the white-cell count 5700, with 74 per cent polymorphonuclears, 21 per cent lymphocytes, 2 per cent monocytes and 3 per cent eosinophils. The average size of the red cells seemed definitely increased, there being many true macrocytes. There were also many small and fragmented forms. The cells were well filled with hemoglobin, and young red cells were few in number. The platelets occurred in approximately normal numbers.

The course of the illness is shown in Chart 1. For a time the patient did well on a water extract of liver (Valentine's E-29), but larger and larger doses were required to maintain the red-cell level at or near the 5,000,000

*Instructor in medicine, Harvard Medical School. Associate physician, Massachusetts General Hospital.

mark. The diarrhea never entirely cleared up but at no time were there neurological symptoms.

From November, 1934, to March, 1935, there was transient soreness and desquamation of the tongue. Finally liver by mouth failed to maintain the red-cell level, and liver extract given intramuscularly was resorted to. As much as 6 cc. of Lederle's liver extract, derived from 200 gm. of liver, was needed each week to keep the count normal.

In May, 1935, the patient entered the Baker Memorial of the Massachusetts General Hospital for further study with a view to considering operative procedures. The fragility test of the red blood cells was normal, hemolysis beginning in 0.44 per cent salt solution and becoming complete in 0.30. The icteric index was 60, and the

The patient was last seen on July 29, 1937, when he stated that he was feeling entirely well and had no symptoms of any kind. Examination was entirely negative except for the heart murmurs mentioned above. The red blood-cell count was 5,690,000 and the hemoglobin 90 per cent (Tallqvist). The blood smear showed no abnormal variation either in size or in shape of the red cells; the differential count of the white cells was normal.

COMMENT

This case is reported as one of pernicious anemia that was secondary to enteroenterostomy, and was entirely cured by restoring the bowel to its normal state.

Chart 1 Pernicious anemia due to enteroenterostomy and cured by reoperation

van den Bergh 10 mg per cent. Gastric analysis showed 28 units of free hydrochloric acid after an alcohol test meal, without histamine. The red-blood-cell count at this time was 3,800,000 and the reticulocytes 1.9 per cent. A ray examination with barium showed an anastomosis of what was thought to be the jejunum with the ascending colon. Operation was decided upon.

With massive doses of liver the red blood-cell count rose to 4,800,000. On July 1, 1935, Dr. Arthur W. Allen operated and found about half the small bowel short circuited. The lower half of the small bowel was tied up in a mass of adhesions. Starting from the ileocecal valve, the adhesions were freed until the anastomosis was reached; the latter was then undone and continuity was restored. The patient made a good convalescence. On July 8, he received an intramuscular injection of 6 cc. of Lederle's liver extract, derived from 200 gm. of liver. Two weeks later the red-blood-cell count was 5,000,000, the icteric index 7, and the van den Bergh too low to read.

Ever since then the patient has remained well, with no diarrhea, and has had a great amount of energy. On August 5, 1935, his red-blood-cell count was 5,000,000, there was only one formed stool daily, his appetite was ravenous, and he was able to do a vast amount of work. On July 19, 1936, the red-blood-cell count was 4,800,000.

In regard to the cause of the anemia, it seems easy to postulate improper absorption of the specific substance necessary for the maturation of red-blood cells, according to Castle's theory. Not only might the short-circuiting of at least half of the small bowel account for such a lack, but also the very rapid intestinal rate obviously present in this case would contribute to it. It is difficult, however, to explain the fairly severe degree of icterus in association with a relatively mild degree of anemia or to account for the very rapid drop in the red-cell level on this basis alone. Except for the absence of evidence of very active red-cell regeneration, the picture suggests a hemolytic type of anemia. There is very little evidence of disturbance in liver function, but one cannot help suspecting that the liver was somehow involved. Such questions might be further clarified if liver function tests could be done at the height of the anemia, and compared with tests performed after operative cure had been established.

In any case, short-circuiting operations, which may be life-saving procedures, should be done with caution, using the smallest length of loop possible, and having in mind a possible secondary operation in an attempt to restore normal function to the bowel.

SUMMARY

A case of pernicious anemia, resulting from enteroenterostomy and cured by operative restoration of the normal bowel state, is reported.

ACUTE PANCREATITIS

GEORGE R DUNLOP, M.D,* AND ERNEST L HUNT, M.D†

WORCESTER, MASSACHUSETTS

AT THE meeting of the New England Surgical Society in 1927 papers were presented by Watkins and Hunt in which the clinical experience with acute pancreatitis at Worcester City Hospital was analyzed. Their reports showed an immediate mortality of 50 per cent in the series of 18 cases. In the same year Schmieden and Sebening from a canvass of a hundred clinics compiled results in 1278 cases treated operatively, including 38 of their own. For the entire group the mortality was 51.2 per cent. In numerous other reports both prior to and about that time mortality rates of from 40 to 60 per cent were the rule. Happily, some recent reports show a downward tendency, whether due to better handling or to more success in recognizing milder cases is not wholly clear. In 1933 Finney was able to report a series of 32 cases with a gross mortality of but 37 per cent.

ETIOLOGY

Since Opie's work early in the century, Flexner and a number of other investigators have described the effects of injecting bile and a host of other irritating substances into the pancreatic ducts. Gastric juice, duodenal contents, dilute acids, alkalis, oils, soaps and diphtheria toxin have one feature in common: if they are injected into the duct of Wirsung with enough pressure, an acute hemorrhagic pancreatitis will result. Schmieden and Sebening, writing from the clinic at Frankfurt, Germany, have warned us that many of the minor traumas which a pancreas may receive while the abdomen is open may be sufficient to instigate a full-blown acute hemorrhagic pancreatitis. They cite as an

example a case demonstrated by Walzel in which, during a transduodenal choledochotomy, pancreatic necrosis followed the introduction of a sound through the ampulla of Vater. In this instance the duct of Wirsung was accidentally invaded. The occlusion of the pancreatic duct by ascariis is enough to initiate this disease, and over 50 such cases are reported in the literature. These same writers point out that a mere puncture or biopsy of the gland has been followed by a similar event.

In view of these sound clinical observations that acute pancreatitis may follow mechanical obstruction or some trauma which allows an extravasation of trypsin into the interstitial tissue, it seems hardly necessary to presuppose, as the etiologic factor for all cases, the regurgitation into the pancreatic ducts of one of the digestive juices. So far as has been determined, infection plays even a lesser role in the production of the disease.

Opie was one of the first to demonstrate a small calculus behind the ampulla which effectively occluded the outlet to the bowel and converted the common duct and duct of Wirsung into a common channel. A number of similar cases have been found in subsequent autopsies, but they are not numerous enough to explain more than a small percentage of the cases. It seems reasonable to suppose that any factor that will suddenly and effectively block the exit of the pancreatic juices so that the duct-acinar system ruptures at the moment of active secretion, will allow the active ferments to escape into the interstitial tissues, and will initiate the chain of events that characterizes hemorrhagic pancreatitis. No work has brought this out more effectively than the scholarly paper of Rich and Duff, published early in 1936, in which they demonstrated to their own satisfaction that certain cases of acute hemorrhagic pancreatitis

Presented at the annual meeting of the New England Surgical Society Providence, October 1, 1937.

followed the partial or complete obstruction of the ducts by a metaplasia of the lining epithelium

PATHOLOGY

In this disease the pancreas may present a picture varying from edema and interstitial hemorrhage to marked necrosis with free hemorrhagic gangrene and later sequestration of the entire gland. Chemical peritonitis, suppuration, agglutinative adhesion and formation of cysts may follow if the patient survives the initial disaster. Fortunately for the surgeon, there are several signposts which at operation suggest the need for exploring the lesser omental sac in order to confirm or establish the diagnosis.

On opening the peritoneum there is characteristically an escape of serosanguineous fluid. The presence of fat necroses is usually pathognomonic. These little white areas are usually found in the early stages around the foramen of Winslow and the root of the mesentery. The large and small bowels are uniformly dilated.

Division of the gastrocolic omentum usually reveals more fat necrosis in the lesser omental sac, together with an edematous and darkly mottled pancreas. If the destruction is extensive, parts of the organ may be gangrenous, with multiple hemorrhagic areas beneath the peritoneum which covers the gland. The amount of fluid retained in the lesser sac depends upon the patency of the foramen of Winslow.

Finney reported a series of cases in which a serosanguineous exudate was found in 53 per cent. This was found in 57 per cent of our cases. Finney reported fat necrosis in 76 per cent, while in our cases 71 per cent showed this lesion.

All writers on the subject have emphasized the frequency of associated gall bladder disease (Table 1). Opie brought out, and experience has proved,

Table 1 *Data on Cases of Acute Hemorrhagic Pancreatitis as Reported by Various Authorities*

Type of operation: abdominal drainage 77% gall bladder drainage 11%

that in cases of acute pancreatitis the biliary tract is frequently diseased, although grossly it appears normal to the surgeon at operation. This is

thought by some to be reason enough to drain the gall bladder, even when no stones are palpable. Against this procedure must be set the possibility that infection may be introduced by cholecystostomy, necessitating a subsequent cholecystectomy. One of us saw a normal gall bladder drained for pancreatitis several years ago, where such a sequence of events occurred.

In our series there were 6 cases, or 43 per cent, in which at operations and at one autopsy no gallstones or other evidence of disease of gall bladder or ducts could be found (Table 2). In general

Table 2 *Associated Lesions of Biliary Tract in This Series of Cases*

CASE NO.	TYPE OF PANCREATITIS	CONDITION OF BILIARY TRACT
1	Acute hemorrhagic fulminating	Stones in gall bladder — one in ampulla
2	Subacute exudative	Stone in gall bladder
3	Subacute	Stone in gall bladder
4	Acute hemorrhagic	Negative
5	Acute hemorrhagic	Stone impacted in common duct
6	Acute hemorrhagic	Apparently normal
7	Acute hemorrhagic	Many stones in gall bladder
8	Acute hemorrhagic (severe hemorrhagic)	Negative
9	Subacute hemorrhagic	Negative
10	Acute hemorrhagic	Many stones in gall bladder
11	Acute hemorrhagic	Two stones in gall bladder
12	Acute hemorrhagic	Many stones in gall bladder
13	Acute hemorrhagic	Negative
14	Acute with necrosis	Negative (postmortem)

even the hard-and-fast advocates of the biliary-tract origin of acute hemorrhagic pancreatitis admit a 20 per cent deficit in its observed relation.

In this connection, the paper by Rich and Duff above referred to deserves more than passing mention. They have been bold enough to launch a new idea and support it by arguments and experimental evidence which are persuasive if not entirely convincing. Their conception rests upon the following three factors, which they feel are demonstrable and trustworthy:

(1) The essential condition to the initiation of the acute hemorrhagic episode is obstruction to some part of the duct-acinar system, with rupture from back pressure of the products of the gland's own secretory power.

(2) A constant and specific vascular lesion, characterized by a rapid necrosis of the walls of arteries and veins, is uniformly found in both the human and the experimental cases of acute pancreatitis. To prove this contention, Rich and Duff injected purified trypsin subcutaneously and produced this vascular necrosis, bile and duodenal contents when injected in a similar manner failed to duplicate the lesion.

(3) A newly discovered lesion of the lining epithelium is a cause of duct obstruction. This lesion consists of a metaplasia of the duct epithelium into nodules of stratified cells tending toward the squamous-cell type. Its discovery as a possible cause of obstruction is attributed to Priesel in 1922, and association of the lesion with cysts, lipomatosis and necrotic foci to Balo and Ballon in 1929. Of their series of 24 autopsied cases this type of obstructing metaplasia was found in one or more ducts in 13. In 150 routine autopsies for conditions other than pancreatitis in individuals over twenty-five years of age it was found in 18.6 per cent, and was associated with old or fresh hemorrhages in 20 per cent.

With this lesion in mind, one of us has reviewed the available autopsy sections in cases of acute hemorrhagic pancreatitis put at his disposal by the pathologists of five hospitals.* The sections were from 12 autopsied cases. In only 2 of these were there appearances which could be interpreted as the metaplasia which Rich and Duff describe. Blood vessels showing necrosis of the walls were not uncommon. Typical nodules of metaplasia were found in 3 pancreases from autopsies for conditions other than pancreatitis†.

Assuming the validity of Rich and Duff's contentions, the following sequence of events is logical.

- (1) Obstruction of the pancreatic ducts.
- (2) Rupture of the duct-acinar system, due to back pressure.
- (3) Escape of the tryptic ferments.
- (4) Necrosis of the vessel walls.
- (5) Hemorrhage into the intersutural tissue with necrosis of the gland.

Certainly their conception is sufficiently intriguing to be kept in mind and to be evaluated by careful observation in future cases by both surgeons and pathologists.

SYMPTOMS

Upcott vividly describes the acute fulminating attack thus:

Sudden agonizing pain in the upper abdomen, radiating through to the back, usually occurring after a full meal in a stout person of middle age, rapid thready pulse and extreme collapse, early incessant vomiting, cyanosis of the face and extremities, sometimes of the abdominal wall, constipation and distention of the transverse colon, but not absolute obstruction, local persistent tenderness in epigastrium, contrasted with absence of general abdominal rigidity in the early stages, and, later, development of a swelling above the umbilicus—all these make an unmistakable picture.

In the majority of our cases less violent onset was the rule. Although typically the pain is referred across the upper abdomen, it may be localized in either upper quadrant. The frequency of associated gall bladder disease together with right-upper-quadrant pain explains why acute hemorrhagic pancreatitis is frequently diagnosed as biliary colic or acute gall-bladder disease.

The persistent pain, continuing until shock supervenes, is highly suggestive. A point of maximum tenderness about 5 cm above the navel, elicited by deep palpation, has been observed in several of our cases, and is thought to be a helpful differential point. There is usually extreme

tenderness over the upper abdomen. If the tryptic ferments are draining through the foramen of Winslow into the peritoneal cavity, the examiner will usually find some generalized tenderness associated with rebound pain, pointing to a chemical peritonitis. If the foramen of Winslow is not patent the tenderness will be limited to the upper abdomen. If the lesser omental sac is filled with fluid a mass can be felt, but it is probable that the pancreas itself is seldom palpated. Archibald recommends thumb palpation, by which he says the outline of a diseased pancreas can be clearly defined.

Brocq and others point out that the acute attack is usually an episode in chronic pancreatitis or a complication of biliary-tract disease. If the general practitioner as well as the surgeon would recognize that many instances of so-called acute indigestion are really due to small hemorrhages, edema or mild inflammation of the pancreas, and would check up carefully for possible causes in the biliary tract, it is highly probable that some of the catastrophic attacks could be averted.

Earlier writers found the disease more prevalent in men. Nowadays the pendulum seems to have swung the other way. Schmieden and Sebening,

Table 3 Data on Cases of Acute Pancreatitis

from the largest compilation of which we are aware, state the incidence in women as 77 per cent. The percentage in our group was 71 (Table 3).

DIFFERENTIAL DIAGNOSIS

Inasmuch as the acute fulminating type of pancreatitis presents aspects which may call for quick decision and prompt action, it is well to have in mind a definite plan of approach to the problem. In our process of differentiation we must consider nonsurgical conditions, among which ingestion of corrosive poisons and coronary occlusion are outstanding. The history of onset following food or drink and the character and content of the vomitus—with regard to blood, foreign color, odors, reaction—should quickly orient one as to the ingestion of poison. Coronary occlusion usually occurs in mid-life or beyond, the pain may be

*Worcester City Hospital, Worcester Memorial Hospital, Peter Bent Brigham Hospital (Boston), Children's Hospital (Boston), Palmer Memorial Hospital (Boston).

†Peter Bent Brigham Hospital, Boston.

epigastric but is more often anginous. Dusky pallor is commoner than cyanosis, fibrillation and pulse deficit may occur with subnormal blood pressure. Leukocytosis if present is of moderate degree. An electrocardiogram may give definite aid. In a few hours absence of the signs of an acute abdomen, with probable development of a pericardial friction rub and moderate rise of temperature, clears the picture.

Acute diaphragmatic pleurisy or pleuropneumonia are possibilities which have to be considered, but their association with respiratory symptoms and signs is fairly characteristic and their elimination is relatively easy.

With the above possibilities removed, the various types of acute surgical abdomen are before us. Perforated appendix may generally be diagnosed by the history of onset and the concentration of local signs in the lower right quadrant, specific tenderness and local muscle spasm being the most reliable. Rectal examination may reveal right-sided tenderness, or even a mass. Vomiting is less conspicuous unless peritonitis has developed. Leukocytosis is moderate rather than extreme.

Perforated duodenal ulcer is more difficult to differentiate. Typically the patient collapses wherever he may be and the abdominal muscles splint tightly, vomiting is uncommon, and if it occurs, is rarely more than a sudden emptying of the stomach and does not relieve the pain. Shock may be considerable and the temperature subnormal. The patient lies still, and movement of his body muscles aggravates the pain. Liver dullness may be obscured, and a "scout film" may show a gas bubble under the diaphragm. Leukocytosis appears before the temperature climbs.

Acute intestinal obstruction is most readily recognized through its complex of obstipation, colicky pain, distention of bowels, visible peristalsis, vomiting of upper intestinal contents and a characteristic picture by x-ray film.

Rupture of a distended gall bladder may give a picture somewhat similar to that presented by perforated ulcer. It is usually less violent, however and may be preceded by a history of disease in the biliary tract. Pain, tenderness and muscle spasm spread from the right rib border over the right side of the abdomen more slowly than is the case in perforated ulcer.

Mesenteric thrombosis usually occurs in the arteriosclerotic patient. Ileus develops rapidly, bloody dejections may occur spontaneously or follow enemas. Vomiting, prostration and leukocytosis are to be expected. This condition is not very common, and its elimination is difficult.

In women, ruptured ectopic pregnancy has to be ruled out. Here the history of menstrual ir-

regularity, location of the initial pain, which is often so severe that the patient faints, rapid development of acute anemia with signs of fluid in the peritoneal cavity, and a tender cervix and other findings on vaginal examination, are all helpful.

Attacks of simple biliary colic are fairly definite, and the pain is characteristic. Originating under the right rib border, it stabs through to the back and radiates to the right scapula region. When it is severe the patient rolls about in agony. The attack is afebrile. The white blood-cell count is not elevated. Vomiting is fairly common. The pain may end suddenly by the stones accomplishing its passage, or peter out to dull aching misery if the stone lodges somewhere along the tract. Jaundice then makes its appearance and our diagnosis is confirmed. This is often the stage in which the patient reaches the surgeon, the hypodermic needle of the family doctor having served during the attack.

Cholecystitis may exhibit fever, chills, localized tenderness and sometimes tumor and leukocytosis, according to the degree of infection and the peritoneal irritation, and icterus according more or less to the associated cholangitis or stones in the common ducts.

Acute pancreatitis may be associated with any of these biliary tract conditions, if so, palpation reveals tenderness extending across the epigastrium, at times even to the left costovertebral angle.

Standing out clearly in the complicated possibilities of upper abdominal crises, an attack of acute fulminating pancreatic necrosis with hemorrhage is quite typical. The patient is likely to be in agonizing pain, vomiting often and without relief, mentally alert if not already narcotized, anxious, too sick to express his agony other than by moans, inclined to lie on the right side, which relieves tension in the lesser omental cavity by drainage through the foramen of Winslow, averse to examination, and with distinct tenderness across the epigastrium, where there is deep resistance or a feeling of fullness. Hiccoughs may be persistent and annoying. The abdomen is distended, but not so rigid as in perforated ulcer. With subnormal temperature, thready pulse and low arterial tension, the leukocyte count may reach 35,000 or 40,000. The urine is scant, and usually contains albumin and casts.

There may have been a full meal just prior to the attack, or alcoholic indulgence. Patients are apt to be plethoric, and may be cyanotic from splinting of the diaphragm or some quality inherent in the toxemia. The slate-gray cyanosis of the skin of the abdomen described by Halstead has not been observed by us.

Because of the many variables and complicating factors which characterize the clinical aspects of

all acute disease processes of the upper abdomen, a clear-cut diagnosis of acute pancreatitis cannot always be made. In our series we were right in 6 cases, or 43 per cent, partly right in 4 or 29 per

Table 4 *Preoperative and Postoperative Diagnoses in This Series*

	Total	14

cent, and the diagnosis was missed in 4, or 29 per cent (Table 3). Fifty-seven per cent of our proved cases were associated with gallstones.

LABORATORY AIDS TO DIAGNOSIS

Considerable progress has been made in laboratory aids to clinical identification of the disease. The routine blood counts are invaluable, since they reveal the intensity of the systemic reaction and the extent of blood loss. Hyperleukocytosis, as has been stated, is the rule and develops early. Acute anemia may be evidenced by low hemoglobin and red-cell count, and when present must be correlated with other signs and symptoms. If the diagnosis lies between pancreatitis and ruptured ectopic pregnancy, a low count favors the latter.

Blood-sugar estimations, including the glucose-tolerance test and blood and urine amylase determinations, when considered together and intelligently correlated to the clinical situation, have been found useful by several investigators. Quick, discussing a paper by Upcott, made the surprising statement that in Melbourne following the use of the urine diastase tests at the Albert Hospital the preoperative diagnostic accuracy increased from 30 to 100 per cent.

Not many writers share this enthusiasm. Hyperglycemia has been noted in acute pancreatitis by a number of them. Brocq and Varangot in 72 cases found the blood sugar below 150 mg per cent in but 15, 150 to 200 mg in 25, and 200 mg or over in 34. In a fatal case (Case 6) of our series it was 210 mg the first day in the hospital, 270 mg

on the fourth (operation) day, and 360 mg on the fifth, which was the day of death. The patient in Case 8, who was very ill and was transfused after the operation, had a blood sugar of 400 mg on the day of entrance. Case 5, reported heretofore as one of pancreatic deficiency, reached 360 mg on the eighth postoperative day. Case 10 on the day of operation had a blood sugar of 220 mg. Case 12 one day postoperatively had one of 160 mg. Case 14, a fatal case, which was not operated on, had one of 212 mg. Case 3, a subacute one, showed the normal figure of 110 mg. Thus, 6 of 7 cases in which blood-sugar determinations were made were definitely well above the high normal mark, this harmonizes with the findings of Brocq and Varangot, who feel that in acute abdominal crises a blood sugar of 200 mg or over may be significant of acute pancreatic necrosis. Wildegans declares that blood sugar elevation occurs in every case of acute necrosis and designates it as a "certain early symptom." Elman warns that diabetics may be subject to acute abdominal conditions. Most of us are familiar with the acutely dilated stomach of impending diabetic coma.

The estimation of amylase in both blood and urine is now practicable, and gives high values in acute pancreatic necrosis. Elman and his associates have done much work with urine-amylase determinations, and recommend that they be made in all cases of acute disease of the upper abdomen. They warn that the rise of urine amylase must be 1000 Wohlgemuth units or more in order to be suggestive of acute pancreatitis.

It also seems clear that the blood lipase is elevated along with the amylase. We were unable to find a test for lipase suitable for clinical use.

For most of us the blood-sugar estimations and the Wohlgemuth test for urine amylase are practicable, and our laboratories should be prepared to support the clinician with these aids at short notice and at any time.

Confronted with such a clinical problem, if one has considered these differential points and observed and weighed the findings, in case doubt remains, exploratory laparotomy becomes an imperative diagnostic measure.

TREATMENT

It is well recognized that the disease varies greatly in intensity. Whatever the accident may be which ushers in the attack, if enough of the gland is involved in the ensuing necrosis, the patient dies. Two of our 14 cases were of this type. Both succumbed—1 with and 1 without operation. A few cases—83 of the 1510 covered by Schmiedens

report—recover spontaneously. Between these extremes lie 85 per cent of the cases which by accepted practice have been treated operatively. The optimum time for operation is subject to considerable difference of opinion.

Of late there has been a tendency to delay operation unless the diagnosis is too obscure to justify the chance of waiting. McWhorter noted that among the cases collected from his Chicago colleagues the mortality was lower in the group operated upon two weeks after the onset.

Eliason and North, who have followed the common practice of operating promptly, found upon analysis of their cases, which like our own numbered 14, that of 8 cases with immediate opera-

In 1908 Glaessner showed that 8 cc of trypsin injected intraperitoneally would kill a dog in five hours. Rich and Duff have shown that under certain conditions the pancreas actually secretes active trypsin, consequently it seems fair to suppose that the longer this digestive ferment is allowed to escape into the peritoneal cavity, the greater the harm to the patient.

Based upon our experience, we believe that operation at the moment which seems best to the competent and experienced surgeon will in the long run give the best results. Such a surgeon

Table 6 *Type of Operation Performed in This Series of Cases of Acute Pancreatitis*

will not operate upon the moribund, will allow no unnecessary loss of time in the fulminating case and will not hurry in the less acute, where he sees a chance of improving the patient's chances by delay. He will not neglect suitable measures to combat shock, relieve emesis and restore fluid and acid-base balance, while preparations for operation are going forward.

The surgical aims in the treatment of this disease may be summarized as follows:

- 1 To complete diagnosis by the accurate method of visualizing the lesion.
- 2 To offer an escape for the tryptic ferments and the toxic products of necrosis by draining the lesser omental sac.
- 3 To relieve the intrapancreatic tension by multiple nicking or incising of the peritoneal covering of the gland.
- 4 To decompress an obstructed pancreatic-duct system by drainage of the biliary tract by whatever method is appropriate to the patient's condition and type of lesion found.

The lowest mortality in McWhorter's and our series was found in the groups where all these procedures were carried out. Needless to say, the operation should be conducted with every provision for supporting the patient's vitality. Anes-

tion 6 died, while of 5 cases with operation deferred four to nine days all recovered. One patient moribund on admission was not operated upon and succumbed. Interestingly enough, our own cases constitute a group clinically similar to theirs, except as to the relation of time of operation to fatal outcome. They were numerically the same, 1 case being moribund and not operated upon, and the remainder all being operated upon at periods varying from seven hours to sixteen days after onset with but 2 deaths. Five patients were operated on within thirty-six hours, and all lived. Two operated on at forty-three and forty-eight hours respectively, lived. Of 3 who were operated upon on the fifth and sixth days 2 died. The remaining 3, operated upon on the tenth and the sixteenth days and after an indefinite period respectively, recovered. While we admit that our cases may have been on the average less severe than Eliason and North's, we believe strongly that in 2 cases prompt operation saved the patients' lives, while in another, delay from the second to the fourth day sacrificed the patients only chance of survival.

thetia planned for minimal toxicity, a speedy and nontraumatic operative technic and transfusion should be among them. Ample and effective drainage of the pancreas must be secured and maintained until nature discards all necrotic remnants of the gland. Postoperative complications must be met as they arise. Hemorrhage, pancreatic asthenia, defective wound healing and diabetes may each or severally be encountered. Recurrence of the disease is not unknown.

A word needs to be said about intravenous glucose therapy. As has been pointed out, hyperglycemia is the rule. It has also been noted that pancreatic secretion is stimulated by glucose. If obstruction to the duct is so large a factor in initiating the attacks, this would seem to contraindicate its use. We therefore feel that the administration of insulin may be of greater advantage to the patient. As a practical matter it is suggested that we orient ourselves in this regard whenever confronted by a case. Among the earliest diagnostic measures the blood should be secured for estimation of sugar, chloride and nonprotein nitrogen. A catheter specimen of urine should be obtained at the same time. Through the diagnostic venepuncture needle introduce 100 gm of glucose in sterile solution. Let this serve for a glucose-tolerance test. Take additional blood and urine samples at hourly intervals and plot the results for three hours if so much time is available before operation. Make use of some of the urine for amylase estimation. Thus therapeutic and diagnostic methods may be combined to spare the patient unnecessary venepunctures and loss of time.

With an initial hyperglycemia and a lowered glucose tolerance, the patient shows evidence of pancreatic damage. With 200 mg of blood sugar or over in the blood and a urine amylase of 1000 or over, our diagnosis of acute pancreatitis is supported.

SUMMARY

In a study of recent literature and a small series of personal cases, we find acute pancreatitis to figure clinically in forms of differing severity, with the milder types increasingly recognized.

Associated biliary-tract disease is still the apparent cause of more than half the cases.

Attention is called to a new conception of causation advanced by Rich and Duff, of which obstruction by metaplasia of duct epithelium, rupture with escape of trypsin and a specific vascular lesion are the essential elements. Concentrated study of this idea by surgeons and pathologists is urged.

In the acute fulminating cases operation judiciously timed remains the therapeutic measure of choice. Operation is also the most reliable diagnostic procedure.

The diagnostic value of blood-sugar and blood amylase estimations, the glucose-tolerance test and urine-amylase determinations are noted and their clinical use advocated.

Finally, a series of 14 cases are recorded of which 13 were treated operatively with 2 deaths, an operative mortality of but 15 per cent.

DISCUSSION

DR ERNEST L. HUNT, Worcester. I am grateful to Dr Dunlop for his work in looking up the literature on this subject and in compiling this paper. The Rich and Duff conception of the etiology of acute pancreatitis has intrigued me, and through the courtesy of Dr Rich I am able to show a few slides of nodular metaplasia of the duct epithelium.

Obstruction to the pancreatic secretions perhaps deserves a bit more attention than it gets. [Slide.] This is a sketch made to illustrate the new theory. The stone in the ampulla is inserted not to take us back thirty-seven years to Dr Opie's original concept of the ducts being changed into a continuous passage, but rather to emphasize the notion that back pressure in Wirsung's duct resulting from obstruction at the ampulla causes rupture of the duct acinar system, liberating tryptic ferments which in turn cause necrosis and hemorrhage.

It has been shown that the pressure of secretion in the pancreas is generally a bit greater than that of bile in the common duct. This condition is reversed during considerable muscular effort, such as sneezing, which brings the diaphragm and abdominal muscles into action and increases the pressure of bile in the gall bladder to a point far above that reached under normal conditions.

The small spots are put in to indicate obstruction in the minor ducts or ductules from the metaplastic nodules, resulting in the breakdown of the tissue behind them. This process usually causes dilatation of the ductules and sometimes the formation of necrotic foci, which may rupture upon any sudden increase in pressure. The difference in degree is of course indicated by the difference in the

size of the duct obstructed and the nearness to a vessel of considerable size.

[Slide.] Rich and Duff also describe a vascular lesion which they maintain they were able to reproduce by injecting trypsin, or the pancreatic juice obtained by cannula into the subcutaneous tissue of animals. The injection of either of these substances is immediately followed by edema and hemorrhage, and after a few hours the wall of the blood vessels affected show a segmental necrosis. This naturally becomes the point of rupture and of hemorrhage. Rich and Duff consider this lesion typical.

[Slide.] This is also one of Rich's sections showing nodular hyperplasia. It is found in a wide variety of conditions, and he and Duff say they have found it in most sections taken from patients who died of acute pancreatitis. I have not been able to verify this statement in detail, but the sections to which I had access were obviously not cut with any thought of that lesion in mind.

Some of you may have noticed that Dr. Dunlop used the word prophylaxis. By prophylaxis in relation to acute hemorrhagic pancreatitis we imply the care of biliary disease in its early stages, as recommended by Clute, Lahey and others.

[Slide.] This is a photomicrograph of a section of pancreas from an autopsy which was kindly lent by Dr. Wolbach. The cause of death was nephritis and complications. The illustration shows an obstruction due to a basal-cell metaplasia of the duct epithelium exactly like that in Dr. Rich's specimen from a case of acute pancreatitis.

I think we may say that in general the nearer the operation comes to the onset of a severe condition of this sort, having due regard to the factors of safety, the more likely we are to relieve the patient of his disease.

DR. I. J. WALKER Having read Dr. Dunlop's interesting paper in manuscript, I believe that the pertinent points for discussion of this important subject are as follows: (1) consideration of the gross pathological aspects of acute pancreatitis, and (2) treatment of the different phases of the disease. Both are important in influencing the present high mortality attendant upon surgery of acute pancreatitis. In reviewing my own cases, as well as those treated at the Boston City Hospital for the past seventeen years, we may well classify them as acute edematous, acute hemorrhagic, and acute suppurative.

Acute edematous pancreatitis, seen rarely at postmortem, grossly shows no evidence of hemorrhage or suppuration but presents a swollen, edematous organ. Clinically this type has a mild symptomatology as compared with the hemorrhagic type. We have found, as have others, that this type of lesion generally ends in spontaneous recovery. These cases at present are rarely diagnosed as such, and surgery, when carried out, has been deemed advisable only because of mild but persistent symptoms referable to the upper abdomen. Accumulation of a considerable number of these cases in a series of cases of acute pancreatitis will tend to give a low mortality for the disease.

Acute hemorrhagic pancreatitis when seen early presents the well known gross pathological picture, and at a later stage shows gangrene or suppuration. The present mortality of acute hemorrhagic pancreatitis treated early by surgery is about 75 per cent.

In suppurative pancreatitis the infection reaches the pancreas by the hematogenous route, via the lymphatics, or by direct extension. The mortality is lower than that of acute hemorrhagic pancreatitis.

What shall be the treatment of these various phases? Of late much has been written on the conservative or medical treatment of acute pancreatitis, with results ap-

parently as good as or better than those obtained by surgery. The lesions of cases which recover without operation being unknown, we must ask what was the actual pathologic picture. One can be sure that most edematous cases of pancreatitis, and some hemorrhagic ones, will recover spontaneously or by medical treatment. Prac-

tically it appears that if one suspects acute pancreatitis of low grade, as evidenced by symptoms and clinical findings, surgery is not advisable for the disease *per se*, but may be indicated on the basis of an accompanying acute lesion of the gall bladder. Likewise, emergency surgery is contraindicated in those cases of hemorrhagic pancreatitis where shock and toxemia are manifest. Under treatment consisting of parenteral fluids and decom-

Table 2 Duration of Symptoms before Operation

pression of the upper intestinal tract by the Wangensteen method, some of these cases will recover without surgery, and those in which surgery becomes necessary will be better prepared for it.

The treatment of suppurative pancreatitis calls for no special comment, other than that the pancreas should be drained when pus is apparent.

Briefly, immediate surgery is not indicated in cases of

acute pancreatitis with mild symptoms unless for an accompanying acute lesion of the biliary tract, nor is immediate surgery advocated in cases demonstrating shock. It is advised in cases of acute pancreatitis after shock and toxemia have been treated, and when the symptoms and clinical signs do not show evidence of retrogression it is assumed that gangrene or suppuration forms part of the pathologic picture.

The accompanying tables show some facts regarding our

experience with acute pancreatitis at the Boston City Hospital. Table 1 substantiates the recognized incidence of acute pancreatitis according to age and sex. Table 2 demonstrates the high mortality attendant upon early operation. The mortality of 18 per cent for the two- to six-day period is of interest. Study of this group substantiates our experience to the effect that the prognosis is better among cases which are not fulminating, hence not diagnosed early and consequently not operated upon at once, surgery being finally carried out for persistence of symptoms referable to the upper abdomen. None of this group were deliberately treated by conservative medical measures. Analysis of the figures in Table 3 indicates cholecystostomy with drainage as far down as the pancreas as the operative procedure of choice.

DR ROLF LIUN, Boston. During the past year we have had occasion to use the urinary diastase test for a number of patients with pancreatitis at the Boston City Hospital, and have found it of considerable diagnostic value. Briefly, this test consists of adding various dilutions of urine to a 0.1 per cent starch solution and incubating for half an hour. Iodine is then added as a reagent to indicate the end point of digestion. The urinary diastase may be elevated in a number of conditions—acute cholecystitis, common duct stone, carcinoma of the pancreas, acute hepatitis, ulcers invading the head of the pancreas and acute parotitis.

The test must be considered only as an adjunct to the clinical picture and history. In 3 cases diagnosed as perforated ulcer we found elevated diastase in the urine. Operation in each case revealed acute pancreatitis. Two patients who had been submitted to previous biliary tract surgery were studied. One had had a cholecystotomy twenty-four years previously, the other had had her gall bladder removed three months previously. Both had the history and clinical picture of acute pancreatitis and elevated diastasia. They were treated conservatively and recovered.

A case seen last week had the history of acute pancreatitis, with physical findings of acute gall bladder disease. The urine diastase was definitely elevated, and a diagnosis of acute gall bladder disease with associated pancreatitis was made. Both lesions were demonstrated at operation.

Not all patients with acute pancreatitis give elevated diastase values. If destruction of the pancreas is so extensive that little of the external secretory elements remain, the diastase may be subnormal. We have had no experience with such cases, but Millbourn records 12 in 13 cases of acute pancreatic necrosis.

If we are to treat acute pancreatitis conservatively, we might well add two measures to the routine handling. We might place an intubing Levine tube in the duodenum and give repeated small doses of magnesium sulfate through it, thus obtaining increased drainage of the biliary and pancreatic ducts and probably doing as much good as is accomplished by surgical drainage of the gall bladder. Or we might give repeated doses of alkali and neutralize the hydrochloric acid of the stomach, which forms secretin in the duodenum. By such therapy we should prevent the absorption of secretin, which is the most powerful pancreatic secretagogue known, and thereby help forestall further swelling of the pancreas by repeated stimulation.

DR EDWARD L. YOUNG, JR., Boston. The discussion so far conducted gives me the impression that everyone makes the diagnosis of acute pancreatitis easily and accurately

and of course correct treatment can occur only if there is a correct diagnosis.

On my service at the Massachusetts General Hospital in 1936, we were faced with the difficult problems of conservative treatment. We became interested in this type of treatment after reading the article by Mikkelsen in the *Acta chir Scandinav* (75:373-415, 1934) in which it was said that the mortality could be reduced from 60 to 20 per cent by delaying operation for from several days to two or three weeks. I tried this with 1 patient. She finally died of spreading sepsis, which I attempted to drain too late, and which did not affect the pancreas. At a staff meeting, it was found that there were 4 or 5 other cases which had been treated conservatively, all with fatal results, and in none of which damage to the pancreas was shown at autopsy.

DR. EDWARD R. LAMPSON, Hartford, Connecticut. I have been much interested in pancreatitis ever since I started practice, when I had a case of the acute hemorrhagic type. The symptoms pointed to acute inflammation of the gall bladder. Dr. Oliver C. Smith operated. When he opened the abdomen, a blood red mass immediately presented in the wound. He started to put a needle through it, upon which I remarked, "That is not the gall bladder." He insisted that it was, and proceeded to pass the needle, when a profuse hemorrhage occurred. He inserted another needle with a ligature with the intention of doing a cholecystostomy, an operation seldom performed at that time.

The hemorrhage was so great that the remainder of the operation was spent in controlling it. We ran out of gauze, so that the old gauze had to be wrung out in water and used over and over again. Finally three large clamps were employed to control the hemorrhage, and the wound was packed. The family physician and I stayed up all night with the patient. Taking boiled normal salt solution and using a fountain syringe and a fountain pen filler, we gave intravenous saline, a hypodermoclysis under the breasts and saline by rectum. Much to our surprise the patient recovered. On the ninth postoperative day she had a secondary hemorrhage, which was controlled by packing.

In the meantime I had examined the specimen removed at operation, and found that the case was one of acute hemorrhagic pancreatitis. A rubber drainage tube was left in the abdomen for six months, for fear that the pancreatic secretions might digest other organs or form a pancreatic cyst. One morning at the end of that period I was notified that some coffee which the patient had drunk was coming out through the tube. This showed that she had developed a gastric fistula. I had her removed to the hospital and took out the drainage tube, and the fistula closed in three days. I published a record of this case in 1903, and it proved to be the first case of acute hemorrhagic pancreatitis reported in Connecticut.

If I recall correctly, Reginald Fitz brought before the medical profession in this country not only appendicitis but also pancreatitis. He adopted the same pathological classification that we have heard about today: acute hemorrhagic, suppurative and gangrenous.

Judging from the cases that we have had at the Hartford Hospital, I should say that our mortality had been much nearer 50 per cent than the 15 per cent reported by Dr. Dunlop.

As we are all aware, there is now considerable discussion as to whether these cases should be treated expectantly or should be operated upon at once. If the former procedure is adopted and a diagnosis of acute pancrea-

thus is made, and the patient recovers, how can we be sure that the diagnosis was correct?

We have had no experience with the diastase test in urine or blood, and I doubt whether it has been used in enough cases to prove its accuracy. The diagnosis is

difficult under any circumstance, and I have frequently seen cases where a diagnosis of acute pancreatitis made previous to operation was found to be incorrect. In all but the mild cases I prefer immediate operation to conservative treatment.

POSTURE IN ANESTHESIA

ALBERT H. MILLER, M.D.

PROVIDENCE, RHODE ISLAND

IT MAY be stated as a principle that an anesthetized patient should never be placed in a posture which he could not safely assume if he were conscious. The fat dowager who would die within an hour if suspended by the heels will be similarly affected by the Trendelenburg posture while under the influence of an anesthetic. Ill-advised postures are responsible daily for surgical fatalities.

Contrary to common opinion, the so-called Trendelenburg posture, in reality originated by Bardenheuer, of Cologne, is not the most favorable for the anesthetized patient. Trendelenburg, indeed, first described its danger and advised against its use for fat patients. The most favorable posture is the dorsal recumbent one, with the head slightly lowered. Without increasing the cardiac and respiratory load, this posture maintains a cerebral blood pressure higher than that at the cardiac level, and increases the arterial blood supply to the cerebral centers. Unfavorable postures are the lithotomy, with elevation of the pelvis recommended for perineal prostatectomy, and the so-called reverse Trendelenburg postoperative. The prone posture has so bad a reputation that some army regulations strictly forbid the turning of an anesthetized patient from the dorsal to the prone posture.

With the aid of a synchronous pneumograph we have shown that the difficulty with the prone posture is partly if not wholly respiratory.¹ All anesthetics with which we are acquainted produce paralysis of the thoracic muscles of respiration. The diaphragm then takes on the entire respiratory load. If the patient is placed face downward on the firm surface of an operating table, the diaphragmatic or abdominal respiration must be carried on under a handicap which may be appreciated by noticing that the patient's buttocks are lifted with each attempt at diaphragmatic inspiration. This handicap may be removed by placing a pillow transversally across the table opposite the anterosuperior iliac spines.

For obtaining the postures desired for many op-

erations in inflatable rubber cushion is more useful than the attachments usually provided with operating tables. The cushion is rectangular, measures 25 by 50 cm. and has a stout rubber tube attached at one corner and terminated by a cut-off valve. It is inflated with compressed air or with nitrous oxide from the gas machine. Oxygen or inflammable gas should not be used, because of the risk of explosion. The cushion should be strong enough to support the weight of an

Figure 1. Gall Bladder Posture. The cushion is inflated until the shoulders are raised from the table and then allowed to deflate until they just touch the table. In this illustration the cushion is allowed to protrude under the arm in order to show its position.

adult. The tube should be long enough to reach the head of the table, where the shut-off valve can be controlled by the anesthetist. The bag should be covered with a fresh pillow slip; it should be frequently sterilized.

For the cholecystectomy posture, the cushion is placed transversally across the table, centered under the ensiform cartilage. When protrusion of the epigastrium is desired, the cushion is inflated until the shoulders are lifted from the table, and then deflated until the shoulders just touch the table when the maximum extension has been obtained.

For thyroid operations, the cushion is placed transversally with its upper margin slightly below

the external occipital protuberance and its lower margin under the shoulders. It is inflated until the occiput is lifted from the table, then deflated until the occiput just touches the table, when the maximum possible extension has been obtained. Care must be exercised not to pin the drappings to the inflated cushion.

Figure 2 *Thyroid Posture* The cushion is inflated until the occiput is lifted from the table then allowed to deflate until the occiput just makes contact. At the close of the operation the tissues may be relaxed for application of the sutures by allowing the bag to deflate without disturbing the drappings.

For operations on the kidney, the patient is placed in the lateral posture with the lower hip and knee flexed at right angles. The cushion is placed transversally, centered between the lowest rib and the crest of the ilium. The pelvis is fixed by a broad strip of adhesive plaster extending from one side of the table across the upper hip to the other side.

The degree of extension is readily controlled by the anesthetist. The cushion may be inflated either immediately before induction or after the patient has been anesthetized.

Figure 3 *Prone Posture* The partially inflated cushion is placed under the anterosuperior spines slightly raising the pelvis and allowing continuance of abdominal respiration.

For the prone posture, the partially inflated cushion is placed transversally underneath the anterosuperior iliac spines, so as to favor continuance of abdominal respiration. A cushion provided with an extra long tube may be placed under the knees to secure relaxation of the abdominal muscles through flexion of the hips and knees, often desirable while suturing an abdominal wound. While these are the chief uses of the surgical posture cushion, other advantages will be discovered through habitual use.

RUPTURED ANEURYSM OF THE LEFT COMMON ILIAC ARTERY SIMULATING PERINEPHRITIC ABSCESS

ISADORE J ZIMMERMAN, M.D.* AND CLARENCE E BUTTERFIELD, M.D.†

MANCHESTER AND CONCORD, NEW HAMPSHIRE

A SEARCH of the literature reveals no record of a case of ruptured aneurysm of the common iliac artery simulating perinephritic abscess. Only one case of ruptured aortic aneurysm simulating perinephritic abscess was discovered¹

The incidence of aneurysm of the common iliac artery is relatively low as compared with that of all other aneurysms. Matas² found only 2 cases in a study of 172 aneurysms. Garland³ discovered only 1 case of aneurysm of the common iliac artery among 167 aneurysms found in the course of 12,000 autopsies. Lucke and Rea⁴ found not a single case among 321 aneurysms.

While perinephritic abscess may occasionally offer a challenge to detection, many less common or rare conditions may readily be confused with it.⁵ The case here reported apparently falls into the latter category.

CASE REPORT

A 57-year-old man, married, was brought into the New Hampshire Memorial Hospital by Dr G Gaudrault, of Concord, in whose office he had fainted. At that time Dr Gaudrault had felt a pulsating mass in the lower left quadrant. However, in view of all the subsequent findings and the absence of pulsations during the entire period of hospitalization, little stress was placed upon this finding.

Because the patient was very restless and incoherent, no adequate history could be obtained, and only a vague and fragmentary one was contributed by his wife. The patient had sustained a broken nose 25 years previously and a blow on the head 12 years previously. No history of abdominal trauma could, however, be elicited. Except for occasional sore throats and some diurnal frequency and nocturia, the patient had apparently voiced no complaints. Five days before admission he confided to a friend that he had pain in the region of the left kidney which was becoming progressively more tender. Questioning of the patient's wife elicited a history of recent skin infection as well as a vague suspicion of hematuria.

Physical examination revealed an obese, obviously sick man whose abdomen was considerably distended. The right side of the abdomen was tympanitic and non-tender. The left flank bulged somewhat. The entire left side was resistant to palpation, and was dull and very tender from the costal margin to the pelvis. The greatest tenderness seemed to be in the region of the left costovertebral angle. The patient complained continually of pain in the lower left quadrant and left back, faintness, headache and nausea. From time to time he vomited. The respirations were about 24 and the pulse ranged from 84 to 100. The blood pressure was 180/90. The temperature ranged from 98 to 103°F., and on the 2nd day of hospitalization the patient had a chill lasting 3 minutes.

On the day of admission the white blood-cell count was 13,000 with 88 per cent polymorphonuclear leukocytes, 11 per cent lymphocytes and 1 per cent monocytes, the red blood-cell count was 4,100,000 and the hemoglobin 85 per cent. The urine was acid, with a specific gravity of 1.036 and no albumin, sugar or acetone. The urinary sediment showed approximately 75 pus cells per high-power field. The Wassermann and blood Hinton tests were negative.

Intravenous pyelograms taken on the 2nd day of hospitalization revealed a clear kidney outline on the right, with normal delineation of the pelvis and ureter. There was good visualization of the right iliopsoas muscle. Considerable gas was present on the right side. The entire left side of the abdomen from the diaphragm to the pelvis was rather opaque. The left kidney could not be visualized, nor could the left iliopsoas muscle be discerned. The patient was then referred to the urological department. He was obviously too sick for further studies or procrastination. Because of the history and findings already given, the diagnosis of perinephritic abscess was made, and since the patient was steadily losing ground immediate drainage was advised.

Hypodermoclyses of salt solution were given. Under spinal novocaine, supported by Nembutal and ephedrine sulfate, an incision was made in the left loin. When it was carried down to the perirenal fascia a large, bluish, bulging, rather extensive mass presented itself. Upon cutting of the fascia the mass was found to consist of freshly clotted blood, together with apparently older clot. The kidney was deeply buried in this sanguineous mass. Exploration in the region of the pelvis revealed a spongy mass about the size of a grapefruit. Removal of a piece of the mass showed it to consist of old, white, laminated clot. The patient's condition immediately became poor. Because of a sudden and uncontrollable swelling of blood into the wound, a large pack was inserted and the wound was quickly closed. The patient's condition on leaving the operating room was critical, and he expired within a few minutes.

An autopsy restricted to the region of the lesion revealed an aneurysm of the left common iliac artery, which had apparently perforated several days prior to operation, causing a slow extravasation of blood into the retroperitoneal space formed by the downward extension of the two layers of the perirenal fascia. The aneurysm included the entire left common iliac artery from the point where it arose from the abdominal aorta to where it gave rise to the external iliac and hypogastric arteries. The rupture occurred on the posterolateral aspect of the aneurysm, and more superiorly than inferiorly. Thus the rupture was retroperitoneal and lateral. The perirenal fascia, which surrounded the kidney and its fatty capsule in the form of a loose sheath, was open inferiorly, the two layers remaining separate all the way down to the pelvis. The anterior layer crossed the great vessels in close apposition medially to join the corresponding layer of the opposite side. The extravasated blood had therefore taken the only course open to it and had spread up between the layers of the renal fascia, with the result that the symptoms were those of a perirenal lesion.

VOLVULUS

A Study of Twenty-Two Cases

EDWARD D. LEONARD, MD,* AND SIDNEY DEROW, MD†

NEWTON, MASSACHUSETTS

TWENTY-TWO cases of volvulus operated upon in the past ten years at the Newton Hospital have been studied in detail in an effort to determine the factors that may contribute to the mortality in acute intestinal obstruction. Acute ileus still has a mortality rate ranging between 40 and 60 per cent. Volvulus accounts for approximately 15 per cent of all acute obstructions. Because of the similarity in the symptoms and treatment in the various forms of acute ileus, the conclusions drawn from this study are applicable to all types of the condition irrespective of the cause. There were 10 deaths in our series of 22 cases—a mortality rate of 45 per cent. The more important facts ascertained by this study are as follows:

Sex

There were 13 males with 6 deaths, and 9 females with 4 deaths. There was a greater prevalence of volvulus in men, but no definite relation of sex to mortality was apparent.

Age

The youngest patient was ten years of age, and the oldest eighty. Volvulus appeared to be evenly distributed in the different age groups, 11 patients being under forty and 11 over forty. Three of the 10 deaths occurred in the former group, and 7 in the latter—mortality rates of 27 and 64 per cent respectively. In this condition, therefore, as in others, age appears to play an important role in mortality.

Symptoms

The two cardinal symptoms in this series were abdominal pain and vomiting. The pain was of the colicky, intermittent type. Its location depended on the site of the obstruction. There were 4 instances of pain in the right lower quadrant, which were thought to be appendicitis. One case was provisionally diagnosed as ruptured ectopic pregnancy and another as perforated peptic ulcer. The

remainder were diagnosed as acute intestinal obstruction.

Vomiting was present in 21 cases, it was not mentioned in the history of the remaining case. The amount, character and frequency of the vomitus were determined by the height and severity of

Table 1 Comparison of Symptoms

SYMPTOMS	SMALL BOWEL LESIONS		LARGE BOWEL LESIONS		ALL LESIONS	
	No of Cases	Per Cent	No of Cases	Per Cent	No of Cases	Per Cent
Abdominal pain	16	100	6	100	22	100
Vomiting	16	100	5	84	21	95
Constipation	5	30	5	84	10	45
Distention	6	37	5	84	11	50

the obstruction. Patients with high occlusions complained more of this symptom than did those with low occlusions. Fecal vomiting was noted in only 4 cases, 2 of which terminated fatally. Too frequently one is inclined to wait for the vomitus to become fecal before making a definite diagnosis. This type of vomitus occurs as a late sign and denotes a poor prognosis.

Constipation has long been thought to be a cardinal symptom of acute intestinal obstruction. Its absence has frequently delayed a diagnosis. In our series this symptom was noted in only 10 cases—five times in the 6 cases of large bowel volvulus, and five in the 16 cases of small-bowel occlusion. One patient with high obstruction complained of diarrhea. Constipation is therefore of value as a diagnostic aid in obstructions of the large intestine, but its absence should never rule out an obstruction above this level.

Distention is also too often awaited in making a diagnosis of acute ileus. In the series studied it was noted in 11 cases. 5 of the 6 cases with large bowel volvulus, and 6 of the 16 with small bowel volvulus. It ranged in severity from slight to marked.

Abdominal tenderness and rigidity were rare findings. They usually indicated necrosis of the bowel wall.

The temperature was apt to be subnormal at the onset. A rise in temperature and in the white

†Junior surgeon, Newton Hospital.

blood-cell count denoted damage to the bowel wall and early peritonitis

Duration of Symptoms

Careful analysis of this factor shows positively that the location and severity (amount of vascular occlusion) of the obstruction are of prime significance. The preoperative period in the entire series varied from twelve hours to seven days. Of the 10 fatal cases, 9 showed volvulus of the small intestine and 1 volvulus of the large intestine. The duration of symptoms in the former group ranged

Table 2. *Average Duration of Symptoms*

TYPE OF LESION	DURATION IN FATAL CASES	DURATION IN NON-FATAL CASES
Small intestine	2 days (3 cases)	16 days (7 cases)
Large intestine	6 days (1 case)	3.5 days (5 cases)

from twelve hours to five days, the average being forty-eight hours. In the recovered patients with small-bowel volvulus the average duration was thirty-eight hours. The patient with fatal large-bowel volvulus complained of symptoms for six days before operation. The surviving large-intestine cases presented an average duration of three and a third days. This indicates that a patient with a volvulus of the large intestine that does not completely stop the vascular flow may survive after a relatively long preoperative period, while one with a high, complete occlusion will succumb if operation is delayed only an hour or two. Delay in the latter group means that simple untwisting will no longer suffice and that extensive operative procedures are necessary to remove necrotic bowel. This need for immediate operation in high lesions is strikingly proved by the slight difference in the duration of symptoms between the fatal and the surviving cases of volvulus of the small intestine—forty-eight hours, as compared with thirty-eight. The delay of ten hours may have accounted for the fatalities.

Operations and Findings

As already stated 16 cases of small-intestine volvulus accounted for 9 deaths and in 6 cases of large-intestine volvulus there was only 1 death. The mortality rate in the small-bowel group was thus 56 per cent, and that of the large bowel group 16 per cent.

Small-Bowel Lesions There were 11 cases of involvement of only one loop, and 5 of involvement of the entire small intestine. Four patients gave a history of a previous operation for another condition. One of these operations was for perineal repair, done three days before. Another was for suture of a traumatic perforation of the small intestine, done six days before. Both these cases ter-

minated fatally. A shortening of the mesentery due to calcified tuberculous glands was the causative factor in a twelve-year-old patient and a fibrous band at the site of an appendectomy done some years before in another. The causes of the twisting in the remaining 12 cases could not be definitely determined. The twists varied in degree from 180 to 360°. Seven of the 9 deaths in this group followed more extensive surgery than simple untwisting. There were 5 enterostomies and 2 resections, all of which cases had a fatal termination. Lobar pneumonia and paralytic ileus were the causes of the other 2 deaths.

These findings emphasize the danger attended with extensive operations on patients that are already poor risks for even minor surgical manipulations. Operation before the onset of necrosis would undoubtedly have presented a different picture. Enterostomy as a treatment for distention is fast falling into disrepute. "Stripping" of the intestine is likewise becoming a thing of the past. Astonishing results are frequently obtained by nasal catheter drainage of the stomach, especially when mild suction is applied.

Large-Bowel Lesions Abnormal lengthening of the mesentery of the colon was the predisposing cause in all 6 cases. The fatal case was that of a seventy-year-old woman who had had symptoms of obstruction for six days. A volvulus of the cecum and ascending colon was found at operation. Because of necrosis of the bowel wall a Mikulicz operation was performed, but to no avail. This patient had been operated on fifteen years previously for a volvulus of the same portion of the intestine. There were 3 other cases of involvement of the ascending colon and cecum. Two of these were treated by simple untwisting. In the third there was a recurrence four months after operation. At the second operation it was deemed necessary to resect the involved portion, not because it was necrotic, but because it was so distended and atonic and the mesentery was so long that future recurrences seemed inevitable. A Mikulicz procedure was carried out. This patient made a delayed but good recovery and was in normal health when last seen two years after the second operation.

There was 1 case in which volvulus of the sigmoid recurred. The patient, a sixty-year-old male, was operated on and was relieved by simple untwisting. One year later the volvulus recurred. The bowel was distended and atonic, as in the case just described. Owing to the poor condition of the patient resection was out of the question and simple untwisting was all that could be done. He was in good health and had had no recurrences one and a half years after operation.

A procedure carried out on all the large-bowel cases with excellent results consisted in the insertion of a long rectal tube high in the rectum at operation. The tube was then worked up into the sigmoid, and even above it, in order to deflate the markedly distended colon after the untwisting. Closure of the abdomen was thus facilitated and disagreeable postoperative complications were averted.

Anesthesia

Nitrous-oxide and oxygen, followed by ether anesthesia, was used in 20 cases, and spinal anesthesia in 2. There were 9 deaths in the former group and 1 in the latter. Obviously no conclusions as to what type of anesthesia is safest can be drawn from so small a series.

* * *

It is no doubt true that preoperative and postoperative saline infusions are of great importance in abating the mortality of this condition. The enormous loss of blood chlorides associated with continued vomiting is a vital factor in the severity

of the disease, even when no necrosis of the bowel has taken place. Numerous observers have emphasized the need for replenishing this loss. The age and general condition of the patient also play a significant role in the mortality. But with knowledge of the mechanism and cause of the obstruction we believe that the most important factors are early diagnosis and early operation. It is obvious that only by these means can the mortality in cases of volvulus be appreciably decreased. This study bears out the old surgical dictum "The longer a patient with acute intestinal obstruction lives before operation, the sooner he dies after it."

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., Editor

CASE 24091

PRESENTATION OF CASE

A twenty-three-year-old, white, New England farmer entered the hospital with the complaint of lung trouble of eight years' duration.

About eight years before entry he began to spit up small amounts of blood. There was no cough at that time, but one month later he developed loud wheezing respirations and began to notice dyspnea on exertion. The wheezing disappeared in about six months, but the hemoptysis continued. He had no fatigue, night sweats, weight loss, chills or fever. Over a period of a year, four years before entry, he had three attacks of "bronchial pneumonia," characterized by cough, hemoptysis, fever, malaise and moderate weight loss. Following the last attack he continued to cough with accompanying dyspnea and hemoptysis. Five months later he had an attack of gastrointestinal disease consisting of fever and diarrhea which lasted for one month. His physician made a diagnosis of tuberculosis and sent him to a sanatorium in Arizona where he remained for a year. While there his sputum was said to contain tubercle bacilli on only one occasion, but this could not be verified on subsequent examinations. Treatment at the sanatorium consisted of the usual sanatorium regime and crushing of the left phrenic nerve. He was advised to have a left thoracoplasty but refused it. He felt well during his first six months there but during the last six months lost 20 lb in weight. He returned to New England two and a half years before entry and spent six months in an outside hospital. Bronchoscopic examination there was said to show a tumor pressing on the left bronchus. After discharge from there, he continued to have a chronic cough and raised moderate amounts of yellow sputum sometimes tinged with blood. He also had marked dyspnea on exertion and some palpitation. His appetite, however, was excellent, and his general health was good.

There was no history of exposure to tuberculosis. In early childhood he had had a severe attack of whooping cough accompanied by "bronchopneumonia." His past history and family history were otherwise negative.

Physical examination revealed a well-developed and nourished man in no distress. The blood pres-

sure was 130 systolic, 60 diastolic. The entire left chest was smaller than the right and was flat to percussion, there was no motion on breathing, and breath sounds, voice sounds and tactile fremitus were practically entirely absent. The right lung and abdomen were negative.

The temperature was 98.6°F, the pulse 80. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,950,000 with 75 per cent hemoglobin, and a white-cell count of 16,200 with 91 per cent polymorphonuclears. The sputum showed numerous polymorphonuclears, a few hemolytic streptococci, numerous alpha-hemolytic organisms, *Neisseria catarrhalis* and *Hemophilus influenzae*.

An x-ray of the chest showed homogeneous dullness obliterating the entire left lung field. The heart and mediastinum were displaced toward the left, and the only air in the left chest was apparently within the herniated portion of the right lung. The left main bronchus was not seen, but the right was quite distinct. The ribs on the left side were markedly thickened, particularly along the axillary line. The ribs were otherwise normal. The gas bubble in the stomach was at the level of the tenth rib. The right lung was clear.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES. In the first film the obvious findings are the complete dullness on the left side of the chest, the absence of the heart shadow on the right and a somewhat emphysematous right lung. In the lateral view the posterior half of the chest seems to be fairly normal, and that would place the dullness in the upper rather than the lower lobe. This dark area is probably due to a herniation of the right lung through the mediastinum. We have a number of films taken using a higher voltage and longer exposure to bring out the structure of the involved lung, and you can now see that the trachea is displaced toward the affected side and that the bronchus to that part of the lung is not well shown. We have the appearance of collapse of the left upper lobe without other evidence of cause.

DR. FREDERICK T. LORD. Does it account for the density?

DR. HOLMES. No, but I do not see any other explanation. It could be collapse or consolidation. I do not believe it is encapsulated fluid.

DIFFERENTIAL DIAGNOSIS

DR. LORD. With respect to the history we have hemoptysis out of a clear sky and that means one of only a few possibilities, tuberculosis is first, cancer second, and the third might be one of the

following bronchiectasis, which rarely gives rise to hemoptysis out of a clear sky, rupture of a lymph node into the air passages, syphilis of the trachea and bronchi, and in other parts of the world, *Distoma vivax* and echinococcus disease. It seems obvious that this patient has a bronchostenosis. The history, physical examination and x-ray are all consistent with it. The physical signs are not distinctive but are wholly consistent with a bronchial obstruction. One may go further and say that in addition to bronchostenosis he has a disturbance in the part of the lung distal to the obstruction. One cannot know exactly what the nature of that disturbance is, but at least it is fair to say that he has atelectasis and he has had attacks of bronchopneumonia, doubtless due to trapping of infection. He probably has chronic inflammatory changes in the affected region and perhaps bronchiectasis or abscess.

The important matter to decide is why he had bronchostenosis. There are a good many causes of bronchostenosis. In the first place a foreign body is a very common cause. It has to be remembered that his disturbance started at the age of fifteen. He could have had a foreign-body inhalation and not have been conscious of it, but this is not a typical history because we do not expect hemoptysis as a presenting symptom out of a clear sky. So I am not inclined to think it is a foreign body which might be radiotranslucent so that one would not find it on x-ray film. It might be stricture from an inflammatory process and resulting scar tissue, but again we do not expect it to give this history of bleeding. I am not inclined to think seriously of it.

He might have syphilis of the trachea and bronchi. Syphilis of the bronchi is rare but does occur and may give rise to just such a disturbance as this, with bronchial obstruction and secondary changes in the affected region. However, one would expect other indications of tertiary syphilis.

Tuberculosis has to be considered. There was one apparently positive sputum but subsequent examinations were said to be negative. No mention is made of a search for tubercle bacilli in the sputum in this hospital. Do we know about that?

DR TRACY B. MALLORY: I can find no record of the sputum.

DR LORD: There is still another possibility. It is most likely that this is a new growth in spite of the fact that it began at fifteen. Without bronchoscopy it is almost never possible to be certain of the nature of bronchial obstruction, but one could guess at what this might be, and I should feel that tumor was the most likely possibility. In view of the long duration and the maintenance of good general health, adenoma of the bronchus—a benign new growth—is most likely. How-

ever, one would want a bronchoscopy under these circumstances to tell more nearly the nature of the obstruction.

DR MALLORY: We stopped this case short before the bronchoscopy because in cases of this sort bronchoscopies often give us the complete answer. I think it did here. Perhaps Dr. Tobey will tell us about it.

DR HAROLD G. TOBEY: I was interested to see in the record that early in the disease this patient developed a wheeze that apparently disappeared later when his obstruction became more complete. It is surprising that the diagnosis of asthma was not made at some time or other. A tumor in the bronchus, as it enlarges, very often causes an expiratory wheeze for some period of time.

As for the history of his bronchoscopies, he had one before he came here. I do not know what the diagnosis was at that time. At bronchoscopy here, the left main bronchus, beginning about 10 cm from the carina, was completely filled with a soft mass which bled very freely. At the first session we removed a large mass which we supposed to be tumor, but as I understand it, it was nothing but granulation tissue. The idea of these repeated bronchoscopies was to clear the left main bronchus. At the second bronchoscopy another large mass of tissue was removed, some of which was blood clot, but one fragment of tumor was obtained. At that time the remaining mass was coagulated with diathermy. Still we were unable to demonstrate the left upper lobe bronchus.

At the last bronchoscopy still more tissue was removed and while we did not demonstrate to our satisfaction the opening of the left upper lobe bronchus, I am sure we did get below it, diathermy was used again. I went away from Boston at that time but the understanding was that bronchoscopies should be continued. It hardly seems possible that after a period of eight years with this increasing obstruction we shall be able to clear the bronchus enough to enable the lobe to fill out again and become completely aerated.

PREOPERATIVE DIAGNOSIS

Benign adenoma of the bronchus

DR. LORD'S DIAGNOSIS

Probable adenoma of the bronchus

ANATOMICAL DIAGNOSIS

Adenoma of the bronchus

PATHOLOGICAL DISCUSSION

DR MALLORY: Two out of the three bronchoscopy specimens showed tumor. This tumor was very characteristic histologically of what we have

been calling bronchial adenoma. What the tumor actually is, is very far from certain, but histologically it looks much more like the carcinoid tumors that we see in the intestinal tract, especially in the appendix, than like any other tumor. Its relation to carcinoid is rather borne out by its clinical behavior. It is extremely slowly growing and very late to metastasize, and yet from the histologic point of view is very apt to be invasive. One of our cases has metastasized to one of the bronchial nodes. In the other cases that we have had a chance to examine the bronchial nodes have been negative. In most cases, however, there has been a slight degree of invasion of the bronchial wall so that the tumors cannot be classified as benign. They are the lowest possible grade that you can call malignant. The problem of how to treat them is a very real one. The duration of the disease or the length of time which will elapse before you may expect metastasis is so great that one hesitates to be too radical. But the tumor is a lethal agent not directly from its neoplastic qualities but secondarily because of plugging of the bronchi and infection and eventual destruction of the distal lung tissue. So unless the bronchi can be kept clear one may assume the patient will die from pulmonary infection.

We have experimented with different kinds of treatment, but I believe the Thoracic Clinic has not yet decided what is the wisest thing to do. I shall ask Dr King to tell us about that.

DR DONALD S KING: Five lines of treatment were possible in this case: first, removal of the tumor through the bronchoscope, secondly, x-ray treatment, thirdly, radium treatment, fourthly, total pneumonectomy, fifthly, leave well enough alone. In spite of the fact that the patient had had very few recent symptoms, it was probable on the basis of our experience that there was extensive suppuration in the atelectatic lung, and that removal of the permanently damaged lung would be the best procedure. However, Dr Churchill believed that extensive adhesions would make removal extremely difficult and hesitated to operate. The next question was as to the implantation of radium seeds, but Dr Holmes believed that he could deliver at the site of the tumor as much radiation by x-ray as would be given by radium and with less danger to the surrounding tissues. X-ray treatment was therefore given, and after a proper interval another bronchoscopic examination was made. The tumor mass was found to be still present, but the histologic changes in the biopsy specimen are of interest.

DR MALLORY: The final biopsy showed the architecture of the tumor pretty clearly but a very small number of viable tumor cells. On the other hand the experiment is not clear cut because Dr Tobey also used diathermy. I cannot say whether

it was diathermy or radiation, but something seems to have killed a good many tumor cells.

DR KING: The next procedure was to attempt removal through the bronchoscope of the tissue which was still obstructing the bronchus. Several bronchoscopies were done, and a good deal of tissue removed. We have not seen the patient for a month, and I am not sure of his present condition.

DR HOLMES: The radium treatment was not so much my idea as that of Dr Belsey. He had spoken of other cases he had seen treated with radium.

DR MALLORY: In London I understand they have been using radium in a special container. Perhaps Dr Belsey would speak of that for a moment.

DR RONALD R BELSEY: At the Brompton Hospital, London, these cases are now being treated by the application of radon seeds to the tumor. Twelve 1.25 millicurie seeds are distributed evenly within the jacket of a tubular platinum container designed by Dr Tudor Edwards. The container is canalized to maintain patency of the bronchial airway, is placed alongside the tumor through the bronchoscope, is maintained in position by a spring for seven days and is then removed.

Six cases treated in this way have been followed bronchoscopically, in 4 there was, at the last observation, no macroscopic evidence of tumor, and in 2 the tumor was greatly diminished in size. In no case did biopsy reveal the persistence of tumor cells. In 2 cases where the bronchus was completely occluded by growth, preventing the introduction of the container, the radon seeds were implanted directly into the tumor with subsequent canalization of the bronchus.

CASE 24092

PRESENTATION OF CASE

A fifty-year-old American housewife was admitted complaining of fever.

The patient was perfectly well until six weeks before entry, when she developed a fever and a rash on her arms, legs and buttocks which was painful to touch and consisted of red, slightly elevated, circular lesions, distributed closely together, and varying in size from 1 to 6 cm in diameter. She went to bed on the first day of the rash, not because of feeling ill but because of the pain she suffered. The acute stage of the rash lasted four or five days and then the lesions began to fade slowly. However, she remained in bed up to the time of entry because of continued fever. She had no other complaints except moderate malaise, some weakness, and a slight cough. She stated that in the past she had been bothered by hot weather and that her symptoms began just after two very hot days.

Except for pneumonia when she was very young, she had had no serious diseases and had had no medical attention since her marriage. She had no weight loss previous to her present illness and no hemoptysis or other symptoms except for slight cough. Her father died of tuberculosis eighteen years previously. One sister died of tuberculosis at the age of twenty-one, and a brother died of it five or six years previously. The patient had not been exposed to tuberculosis after her father's death. A sister died of peritonitis at the age of eighteen. Her mother and five other siblings were living and well.

Physical examination showed a fairly well-developed, somewhat emaciated, chronically ill woman breathing rapidly. There were small discrete hyperkeratotic spots on the exterior surfaces of the arms. The skin was rough and dry, and there were many areas of brown pigmentation on the trunk. There was a walnut-sized node in the left axilla. The chest showed slight splinting of the right side. There were areas of bronchovesicular breathing and fine to medium crepitant rales, with dullness over the lower half on the right and the lower third on the left posteriorly and laterally. The voice sounds and tactile fremitus in these areas were slightly increased. The heart sounds were of poor quality, and there was a distinct gallop rhythm. A_2 was greater than P_2 , and the pulse was weak. There was generalized tenderness of the abdomen. The blood pressure was 90 systolic, 58 diastolic.

The temperature was 100.4°F , the pulse 112. The respirations were 24.

The urine had a specific gravity of 1.010, and a very slight trace of albumin, normal sediment, and no Bence-Jones protein. The blood showed a red-cell count of 4,290,000 with a hemoglobin of 75 per cent. The white-cell count was 5300 with 76 per cent polymorphonuclears. A blood culture contained diphtheroids. Widal and undulant fever agglutinations were negative. The blood gave a total protein of 4.2 gm and a nonprotein nitrogen of 78 mg per cent. The sedimentation rate was 0.52. The blood sugar was 182 mg per cent. Five sputum examinations were negative for tuberculosis. An electrocardiogram on the second day showed diphasic T_1 and T_2 and a P-R interval of 0.20.

An x-ray of the chest showed multiple small areas of calcification at both apices and throughout the left midlung field. The right diaphragm was high, and the right costophrenic angle was obliterated. The long bones showed no evidence of disease.

On the second day her temperature rose to 102°F and for the next three days fluctuated between 100 and 103° . Her pulse remained rapid, and

her respirations rose to 40. On the third day a dry pleural rub was heard in the right axilla and posteriorly, which, however, disappeared in the next twenty-four hours. An electrocardiogram on the fifth day showed a P-R interval of 0.19, low T_1 , diphasic T_2 and T_3 , and a low origin of T_4 with low voltage, suggesting poor myocardial function. A blood culture taken that day was negative. The temperature rose rather abruptly to 105°F and was maintained at that level, with a gradual fall to 103°F at the time of death. On the sixth day the patient developed unilateral edema with increased warmth of the left leg. Marked abdominal distention was relieved by an enema. The lungs were filled with fine crackling rales at the bases and coarse rhonchi elsewhere. On the sixth day the white-cell count was 3300 with 72 per cent polymorphonuclears. She developed a coarse tremor of both arms. On the ninth day a portable chest plate showed consolidation of the lower three quarters of the left lung field. Her condition remained relatively unchanged, and on the eleventh day she died.

DIFFERENTIAL DIAGNOSIS

DR DONALD S. KING: There is one possible diagnosis which recurred so constantly as I read through this record that I cannot refrain from making it. However, the condition is unusual, and although on paper the diagnosis may seem clear, I am almost afraid to make it.

We will let Dr. Holmes take up the x-rays first.

DR. GEORGE W. HOLMES: In the first film there is evidence of tuberculosis of both apices. The shadows are very sharp. It looks as if it were an old process and probably not active. She has an elevated diaphragm on the right side and some increase in the hilus shadows. I do not see the cause of the high right diaphragm unless there is an occluded bronchus running to that area. We have no films in expiration and no lateral view to help us. Eight days later she has a marked change on the left side. I should like it much better if it were on the right side. On the left side now there is an area of consolidation which extends up to the second rib in front, which does not obliterate the outline of the heart or displace it, and which does not obliterate the outline of the diaphragm. I should think it was a pneumonic type of process and not fluid. The high position of the diaphragm on the right has disappeared. It is now nearly normal. In the last film, taken two days after the second, the process is still present and of about the same size.

She has positive evidence of a rather extensive, old, tuberculous infection of the lung. We have not much evidence as to what the acute process is

DR. KING You would not necessarily call this new process tuberculosis?

DR. HOLMES It is a pneumonic process. It could be tuberculous pneumonia.

DR. KING On the basis of the x-ray findings in the lungs, I am willing to throw out a primary lung infection as the cause of this patient's eight weeks of fever and other symptoms. When she came into the hospital, there was no x-ray evidence of active pulmonary disease. On the ninth hospital day, she developed a pulmonary lesion which from the x-ray standpoint, can be terminal pneumonia. Therefore, I do not believe that a lung infection was responsible for her symptoms during the entire eight weeks.

Let us review the facts so that you can see the picture that I have in mind. The patient is a woman of fifty. Fifty years is a little old for the condition, but by no means rules it out. The sex is right. The symptoms began after a hot day. We do not know that she had been exposed to sunlight, but it was in the summer and we have a right to assume that she may have been. There is a strong family history of tuberculosis which is said to be present in a majority of the patients suffering from the disease which I am considering. Whether tuberculosis is the cause of this disease no one has been able to prove, but it is very frequently associated with it. There is evidence of a cardiac lesion probably located in the myocardium. This is also a characteristic accompaniment of the condition. Whether, in this case, endocarditis is present, we cannot say. More than 50 per cent of the autopsied cases reported have shown endocardial changes but not true bacterial endocarditis. In the present case, the kidneys are involved, since the nonprotein nitrogen was 78 mg per cent. However, there is no report in the urine of red cells or casts. So far as the lungs are concerned, we have terminal pneumonia and scattered lesions which could be of vascular origin. There was also a pleural rub, but no evidence of pleurisy with effusion or pericardial effusion, both of which occur frequently. Finally, there is a definite leukopenia in two counts after hospital admission.

Now there is a disease, occurring especially in women, with prolonged fever and leukopenia, with recurring skin lesions brought out by exposure to the sun, and accompanied by vascular lesions in the heart, lungs and kidneys. How can I refrain from diagnosing the present case as lupus erythematosus disseminatus?

But there are some points which are not typical. In the first place, the skin lesions are not the characteristic lesions of lupus erythematosus, which usually persist longer and are apt to be prominent about the fingernails. In the second place, the urine does not show the characteristic changes,

nor was there definite fluid—pleural, pericardial or in the joints.

There is one final argument for my diagnosis namely, that I went this morning to the Treadwell Library to find the volume of the Transactions of the Association of American Physicians in which Dr. Baehr describes 23 autopsied cases of the disease, and found that the book had been taken from the library by Dr. Mallory.

What else can the diagnosis be? Of course, one thinks of erythema nodosum and the skin lesions described are certainly consistent. A terminal tuberculous process might come after erythema nodosum, but this seems to me very unusual in a woman of fifty with fever for eight weeks and acute lung lesions which did not develop until shortly before her death. What other conditions can give skin lesions and fatal pulmonary involvement? Various yeast and fungus infections may give these, but we have no evidence for such a diagnosis. How about bacterial endocarditis? We have the persistent unexplained fever but no other evidence. It is obvious that the men who were taking care of the patient had thought of lymphoma and multiple myeloma and had ruled these out so far as it could be done. There is no evidence for periarteritis nodosum. I cannot make any diagnosis that suits me as well as lupus erythematosus disseminatus.

DR. WYMAN RICHARDSON I have an idea that perhaps too much emphasis has been put on the skin lesions. They lasted only four or five days so far as I can see from the history.

DR. TRACY B. MALLORY They were certainly gone at the time of autopsy.

DR. WALTER BAUER They were not characteristic of lupus.

DR. RICHARDSON The description sounds like erythema multiforme, and I wonder if she may not have tuberculosis of the adrenal glands with pulmonary infarcts to account for the lung picture. The hot-day argument comes in there also, you get hypotension, and many of these findings could be due to adrenal failure.

DR. KING I think my picture is better. If you read the descriptions in the literature, it is perfect. That is the trouble, it is too good.

DR. RICHARDSON Can you have disseminated lupus, sine lupus?

DR. KING Yes, with no skin lesions at all, or with lesions that come and go quickly. I looked up the descriptions of the skin lesions of disseminated lupus, and I think they fit this case.

DR. MALLORY It is unfortunately very nearly impossible to give in words a description of skin lesions that is of much use to anyone. Dr. Bauer was in charge of this patient and he can tell us a little more.

DR BAUER I personally do not think that these skin lesions described are consistent with what we think of as the skin lesions of lupus erythematosus disseminatus. They really are more like erythema nodosum.

When this woman entered the Baker the thing that I wondered about most was whether the skin lesions, which had disappeared, represented an erythema nodosum, and in view of that, whether we were dealing with an individual who had a very severe rheumatic fever, which could explain the whole picture. Knowing that erythema nodosum is also seen in association with tuberculosis, the only other possibility that I could entertain very seriously was that of miliary tuberculosis. I was unable to go any farther than that. I wanted very much to make a diagnosis of rheumatic fever. Before the autopsy I said I should put rheumatic fever first, miliary tuberculosis second, and the question of lymphoma as a distant third, but I really thought the diagnosis lay between very severe rheumatic fever and miliary tuberculosis.

DR KING But you had no real evidence for rheumatic fever, except the unexplained fever?

DR BAUER We had the heart findings which could indicate serious damage to the myocardium, skin lesions which we interpreted as probably being erythema nodosum, and the possibility that the pneumonic infection was a rheumatic pneumonia. I tried hard to make another diagnosis, but I always kept coming back to rheumatic fever. I think I really wanted for once to make a diagnosis of severe rheumatic infection in a woman of this age and thought I had a fair amount of evidence in its favor. When I came to the autopsy room, however, I put miliary tuberculosis first and rheumatic infection second.

DR MALLORY As I read over the story this morning I must acknowledge that I, too, thought of Dr King's diagnosis first.

DR BAUER She never had anything in the kidneys to indicate an active nephritis.

DR KING She had a nonprotein nitrogen of 78.

DR BAUER Yes, at the end.

DR MALLORY I think one should always be cautious about interpreting evidence of renal failure in the terminal stages of a patient's illness. I believe if we took more nonprotein nitrogens the day before death we might get a great many over 80.

CLINICAL DIAGNOSES

Rheumatic fever
Miliary tuberculosis?
Lymphoma?

DR KING'S DIAGNOSIS

Lupus erythematosus disseminatus

ANATOMICAL DIAGNOSES

Pulmonary tuberculosis, chronic, with cavitation
Acute miliary tuberculosis
Tuberculous peritonitis
Pulmonary embolism and infarction
Bronchopneumonia
Thrombosis of left iliac vein
Arteriosclerosis, moderate

PATHOLOGICAL DISCUSSION

DR MALLORY At autopsy we found a diffuse miliary tuberculosis and a tuberculous peritonitis. The peritonitis was the most impressive of the lesions. Every millimeter of the peritoneum was studded with minute, very young tubercles. The heart was entirely negative except for questionable thickening of the endocardium of the left ventricle overlying the septum. The kidneys also were negative. We found an old tuberculous cavity in the left lung and scars of tuberculosis in both upper lobes. So far as the gross appearance of the lung lesions was concerned, we could not make out any evidence of activity. It is not surprising that they saw none by x-ray. The more acute process in the lungs was not tuberculosis but was a combination of multiple infarcts and pneumonia. She had infarcts scattered throughout all five lobes and a large area of pneumonia in the left lower lobe. The source of the emboli was a thrombus of the left iliac vein, which had been the cause of edema of the left leg.

DR RICHARDSON What about the adrenals?

DR MALLORY They were negative.

DR HOLMES Where was the cavity in the left lung?

DR MALLORY It was 3 cm down from the apex in the left upper lobe. It was quite a big cavity, 3.5 cm in diameter.

A PHYSICIAN Did she have meningitis?

DR MALLORY We did not examine the head.

DR JOHN D STEWART Was the walnut sized node tuberculous, too?

DR MALLORY I do not believe we looked for that, however, her peripheral lymph nodes showed tuberculosis.

A PHYSICIAN Do you think the skin lesions were miliary tuberculosis?

DR MALLORY No, I do not think they could have been. My best guess is erythema nodosum which you get with either rheumatic or tuberculous infection. Do you agree, Dr Goodman?

DR JOSEPH GOODMAN Yes.

WHEN IS A PROFESSION NOT A PROFESSION?

THE nature of a profession is such that it is impossible of determination by material standards. One always comes back to a criterion which in some way embodies the spirit of the profession. It is difficult to define this spirit, but without further specification we may contrast it with the commercial spirit as an approximation sufficiently close to definition for the present purpose.

Recently the Supreme Court of Massachusetts handed down an opinion in which optometry is characterized as a profession. The case involved as one defendant a physician whose license had been revoked within the year for association, in the practice of medicine, with an unlicensed person, and seems to have had to do with the same

acts for which the physician lost his license. A transcript of the decision appears elsewhere in this issue of the *Journal*.

The Court weighed the evidence for and against the professional status of optometry and decided that "the placing of optometry on a professional basis" was not arbitrary or irrational. It also expressed the view that professional status is incompatible with the status of a servant. The physician in this case, as employed by the layman, became his servant. How far is the opinion justified in denoting optometry as a profession?

Under the definition of optometry as it once appeared in the statute, the optometrist measured the powers of vision of the human eye and adapted lenses for the aid of vision. Under the definition now in the statute, the field for the optometrist has been much extended and the Court thinks that "the work of an optometrist approaches, though it does not reach, ophthalmology." But the optometrist does actually adapt lenses for the aid of vision and sells spectacles, eyeglasses and lenses for the purpose of correcting vision. In this vending of mechanical devices, the optometrist competes with the optician, in trade, on his own ground. Also, contrary to the usual practice of a profession, an optometric practice may be carried on by the unregistered spouse of a registered practitioner. Is optometry then a profession or a trade? The question is worded in accordance with a type of logic much discredited of late, "either—or." The implications are that optometry is either a profession or a trade, it cannot be both, for a profession and a trade are mutually and reciprocally exclusive. The facts of life often ruin our logic as in this case.

In one part of his work the optometrist is as commercial as the optician, no more and no less. In another part of his work, and this insofar as he is practicing medicine, he is professional. It is sometimes contended that since the legislature has provided for the separate licensing of optometrists, it has taken optometry out of the field of medicine. But it is not in the power of the legislature so to do: an act of legislature can only delimit the legal and the illegal. The induction of an abortion is

the practice of medicine no matter who performs it. How much of the work of the optometrist is professional and how much is trade, it may not be possible to determine easily. The proportions may vary. It is known that often the physician, as in the present case, is paid one dollar for each examination of the eyes, and that nine dollars is a fair average price for the glasses sold to the patient by the optician. Perhaps it is not just to judge the optometrist by this standard—ten per cent professional and ninety per cent commercial—but it is still true that "Where your treasure is, there will your heart be also."

If one examines the statutes concerning dentistry, one finds that, from this point of view, it also is not wholly a profession. The law specifically permits corporation practice of dentistry. Is there any other branch of medicine in which this is possible? Generally corporation practice of a profession is held to be highly improper. Sections 49 and 52 of Chapter 112 of the General Laws use the term "corporate" and "corporation" and Section 53 of the same chapter says further "Nothing in sections forty-three to fifty-two inclusive shall

prevent the widow, executor or administrator of a registered dentist who has died, or the wife of one who is incapacitated, from continuing his business under a registered dentist." It is impossible to reconcile this with the opinion of the Supreme Court that the personal relation between physician and patient is to be regarded as the essence of the profession.

There is a permanent tendency in human nature which works toward the commercialism of professions. It is seen in all of them. It has strong influence in medicine today, even in the main stream where as yet it has received little if any statutory support, and in some of the subsidiary branches it seems to be advancing rapidly.

For various reasons, summarized in the statement that "national health is the greatest national asset," interest in health has become far more widespread than fifty years ago. Preventive medicine is almost the order of the day. Insurance companies, industrial concerns, educational institutions, all have their health programs and render

some form of health service by employing physicians. None of these corporations are eleemosynary in the strictest sense, and some are organized purely for profit. To what extent are they commercializing medicine? Are not hospitals in some cases exerting a subversive influence by their apparently commercial practices?

It is a fact that the practice of medicine has become far more commercialized than is generally recognized. When commercialism becomes dominant, medicine is in danger of losing completely its professional standing. It is the duty of the medical profession to set its house in order. The undertaking is difficult and not without danger. For it, medical statesmen are needed as leaders, and behind and supporting them, an enlightened and united profession.

We need a fresh vision of the deep underlying unity of the healing art, a keener sense of the responsibilities of what may become for all of us a noble profession, and a determination to prevent, and so far as may be, to remove, the stains which commercialism has smeared over the surface. It has not yet touched the heart of the profession. The deeply rooted antagonism between the spirit of a profession and the spirit of commercialism lies in the difference of their aims. The ideal of a profession is the beauty of an esthetic achievement. This the commercial spirit seeks to destroy.

BORROW 175,000 BOOKS FOR \$15!

SUCH an offer suggests the prospectus of a loan shark rather than the duly authorized privilege of any member of the Boston Medical Library in return for yearly payment of dues. Yet the recent annual report of the Librarian of this institution expresses regret that the Library is not more used by its members. What, then, is the reason for this apparent apathy on the part of medical readers?

The evidence suggests that it is not because of inadequate facilities or service on the part of one of the leading medical libraries of the world. The Library offers to its members an unusually comprehensive collection of current periodical literature, as well as standard reference books. Well

over half of the volumes in the Library are not to be found in any other library in Greater Boston. Unusual items may be quickly obtained from the Surgeon General's Library in Washington. Quiet cubicles where members may keep books ready at hand assist scholarly effort. Moreover, the service rendered by the Library is by no means confined to its own premises. Professional memberships in the names of various hospitals and medical schools in Greater Boston allow the staffs of such institutions the use, within the library so affiliated, of any book in the Boston Medical Library. Through the professional memberships of their own institutions, members of the Boston Medical Library may borrow books for use outside of the affiliated library. Inter-library loans afford a service to medical libraries in all parts of New England.

On the other hand, as an explanation of the fact that the use of the Boston Medical Library has increased only slightly during the past year, it cannot be supposed that the profession consults the medical literature less often than in the past. The apparent lack of readers at the Library is probably explained by the increase in facilities for the perusal of the medical literature afforded elsewhere. Thus, as is highly desirable, many of the medical readers of today can turn for their immediate needs to the library of the hospital or medical school with which they are affiliated. Nevertheless, if the necessity for providing adequate financial support for the Boston Medical Library should be lost sight of, almost irreparable injury would be done. Within reason, no amount of development of the smaller libraries of the community can substitute for the vast collections quickly available at the larger institution. This Library is thus an institution with an importance common to all physicians, irrespective of their academic or professional affiliations. By joining, the individual subscriber clearly obtains full value for his dues, and in addition has the satisfaction of knowing that he is contributing to one of the basic resources of the medical profession of Boston and New England.

CASE HISTORY No 61 PARTIAL PLACENTA PREVIA

Mrs. A., a white multipara, aged thirty-two years, had a painless hemorrhage of about 200 cc. of fluid blood in her physician's examining room while she was disrobing preparatory to a routine examination at eight months. She was sent to the hospital immediately.

There was no family history of tuberculosis, diabetes, cancer or hemorrhagic disease. She had had measles and scarlet fever as a child, and her appendix had been removed four years before. She was subject to occipital headaches and had occasional attacks of tonsillitis.

Her catamenial history was normal, with a twenty-eight-day cycle. Two previous pregnancies had terminated in low-forceps operations, and these two children were alive and well. Both pregnancies had been complicated by a mild toxemia without convulsions. The date of her last period was May 19, making the expected date of confinement February 26. She had been seen three times previously in this pregnancy, and at each visit her blood pressure had been found a little above normal. On January 27, the day of the hemorrhage, her blood pressure was 145 systolic, 90 diastolic.

At the hospital her examination showed a normal temperature, with a pulse of 88. Her heart was not enlarged, and there were no murmurs. Her lungs showed no abnormalities. The uterus was symmetrically enlarged, with the fundus about three fingerbreadths below the ribs. The fetus was in ODA position with a steady fetal heart rate of 128 and sounds of good quality. Active bleeding had ceased by the time she arrived at the hospital. The urine showed no albumin.

Two diagnoses were of course brought to mind—placenta previa and partial detachment of a normally implanted placenta from toxemia. It was deemed best not to examine the patient vaginally at once, and no more bleeding occurred during the next five days.

At the end of this time she was taken to the delivery room. Everything was prepared for imme-

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

dite delivery, if necessary, and also a sterile bagging set was on hand. Vaginal examination revealed a placenta previa, with the edge of the placenta just inside the cervix on the left side. The fact that the patient was a multipara with a soft, partially patulous cervix seemed to indicate that delivery from below was the method of choice, and a No. 6 Voorhees bag was inserted into the uterus and filled with sterile water. In the process, some bleeding was encountered because the membranes over the os were very tough and would not rupture after ordinary methods were used. The bag was therefore inserted on the right side of the uterus without rupturing the membranes. The fetal heart maintained a steady rate of 140 throughout.

The bag was inserted at 11 a. m. and at 7 p. m. no progress had been made. There were mild, irregular contractions of the thirty-second variety which did not complete the taking up of the cervix. There was a slight ooze alongside the bag in spite of increased weight being applied to it. The patient was showing signs of fatigue, and the pulse had risen from 80 to 100.

A second attempt to rupture the membranes was deemed advisable. A second bagging set was prepared. After removal of the first bag from the uterus, the membranes were again attacked. The sharp point of the scissors failed to go through, and in exerting the necessary pressure, the hemorrhage became of alarming proportions. Fortunately the cervix was soft and readily responded to attempts at dilatation, and the membranes were finally ruptured by attacking them inside the uterus. The placenta was explored and found to be detached over a considerable area. The Braxton-Hicks procedure was immediately decided upon. A leg was easily found and pulled down through the cervix. Traction on the leg seemed to check the hemorrhage. While preparing to put a weight on the leg, it was noticed that the necessary traction was causing the baby to dilate the cervix. The descent continued until the buttocks were in the vagina when it was decided to deliver the baby immediately. The subsequent delivery was very easy, and the baby, who weighed 7 lb., cried at once. The placenta followed the baby before the cord could be cut.

The cervix was inspected and found to be lacerated in the median line anteriorly. The laceration extended 10 cm. beyond the vaginal vault. This was brought together with a suture which passed through the vaginal mucosa, and the cervical laceration was repaired. There was no other cervical laceration. On account of a slight but continuous ooze the uterus and vagina were packed with gauze.

The husband had been found to be a compatible donor, and a transfusion of 500 cc. of blood was given by the Vincent method. This brought the pulse rate from 140 to 120.

Three hours after the delivery, the pack had shown no signs of staining, and the patient was returned to her room. Fifty minutes later the patient had a sudden severe pain in the lower abdomen and expelled a large amount of fluid blood. The pulse rose immediately to 150, and the patient again showed pallor and some shock.

The diagnosis of rupture of the uterus was made, and the patient was immediately prepared for abdominal operation. On opening the abdomen a hematoma, the size of a hen's egg, was found beneath the peritoneum and a little to the left and just above the cervix. Blood had also invaded the left broad ligament. The uterine muscle in the region of the placental site was friable and torn transversely. The peritoneum, however, was intact. The split above the cervix was successfully closed by the suture inserted at the time of the delivery. A supravaginal hysterectomy was done, 2000 cc. of glucose in saline and a 500 cc. transfusion of blood were given during the operation.

The patient ran an uneventful convalescence, and both mother and baby were discharged well on the twentieth postpartum day.

Comment. This case presents several unusual features. It was the unusually tough membranes that started the train of events that ended in hysterectomy. Rupture of membranes should always precede the insertion of a bag in placenta previa. The distention of the bag undoubtedly detached some of the placenta when the bag was filled and did not exert pressure properly against the placenta, as evidenced by the leaking while the bag was in place.

It is also unusual for a bag to fail to start labor in eight hours in a case where the cervix is soft and patulous. With the lack of labor plus a rising pulse and leakage of blood, it seemed imperative to make endeavors which would bring on labor and correct the leakage, if possible.

The cervix was so unusually soft and dilatable in this case that ordinary traction on the leg of the baby after the version caused it to dilate. In all probability the rupture of the cervix occurred when the head was forced through it by supra pubic pressure, although this pressure did not seem excessive.

The cause of the sudden severe pain in the lower abdomen four hours after delivery, followed by the large hemorrhage, is not clear, unless it marked the time when the subperitoneal hemorrhage occurred. It is possible that a very strong contraction of the uterus, resulting from the irritation of the gauze pack, may have torn the lower uterine segment in the region of the placental site, and that this injured the larger blood vessels. The shredding of the placental site found at operation probably occurred when the head was forced through the cervix, and the contraction of the uterus later added further damage.

ANNUAL MEETING

THE one hundred and fifty-seventh annual meeting of the Massachusetts Medical Society will be held at the Hotel Bradford, May 31, June 1 and 2.

The Shattuck Lecture will be given on Tuesday, May 31, by Dr. David Riesman, emeritus professor of clinical medicine and professor of the history of medicine at the University of Pennsylvania School of Medicine. His subject will be 'Superstitions, Cults and Neuroses.'

MEDICAL POSTGRADUATE
EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 7.

BARNSTABLE

Sunday, March 13, at 4:00 p. m., at the Cape Cod Hospital, Hyannis. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: R. Earle Glendy. John I. B. Vail, *Chairman*.

BERKSHIRE

Thursday, March 10, at 4:30 p. m., at the House of Mercy Hospital, Pittsfield. Subject: Pneumococcus Pneumonia and Serum Therapy. Instructor: Frederick T. Lord. Melvin H. Walker, Jr., *Chairman*.

BRISTOL SOUTH (Fall River Section)

Monday, March 7, at 4:30 p. m., at the Union Hospital, Fall River. Subject: Atelectasis in the Newborn. Instructor: Clement A. Smith. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*.

ESSEX NORTH

Friday, March 11, at 4:00 p. m., at the Lawrence General Hospital, Lawrence. Subject: Atelectasis in the Newborn. Instructor: Warren R. Sisson. John Parr, *Chairman*.

ESSEX SOUTH

Tuesday, March 8, at 4:00 p. m., in the Nurses Home, Salem Hospital, Salem. Subject: Gonorrhea in the Male. Instructor: George C. Prather. Walter G. Pluppen, *Chairman*.

FRANKLIN

Wednesday, March 9, at 8:00 p. m., at the Franklin County Hospital, Greenfield. Subject: Differential Diagnosis and Treatment of Scarlet Fever. Instructor: Edwin H. Place. Halbert G. Stetson, *Chairman*.

HAMPSHIRE

Thursday, March 10, at 4:00 p. m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p. m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject: Rheumatic Infection, Rheumatic Heart Disease. Instructor: T. Duckett Jones. George D. Henderson and George L. Schadt, *Chairmen*.

HAMPSHIRE

Wednesday, March 9, at 4:15 p. m., in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject: Early Syphilis. Instructor: Rudolph Jacoby. Warren P. Cordes, *Chairman*.

MIDDLESEX EAST

Tuesday, March 8, at 4:00 p. m., at the Melrose Hospital, Melrose. Subject: Toxemias of Pregnancy. Instructor: John Rock. Joseph H. Fay, *Chairman*.

MIDDLESEX SOUTH

Wednesday, March 9, at 4:00 p. m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject: Bleeding in the First Trimester of Pregnancy. Instructor: John Rock. Edmund H. Robbins, *Chairman*.

NORFOLK

Friday, March 11, at 8:30 p. m., at the Norwood Hospital, Norwood. Subject: Cesarean Section, Analgesia. Instructor: M. Fletcher Eades. Hugo B. C. Riemer, *Chairman*.

PLYMOUTH

Tuesday, March 8, at 4:00 p. m., in the Rosa Field Nurses Residence, Brockton Hospital (rear of hospital), Brockton. Subject: Complications in Obstetrics Illustrated by Case Histories. Instructor: James C. Jannetty. Walter H. Pulsifer, *Chairman*.

WORCESTER (Milford Section)

Thursday, March 10, at 8:30 p. m., in the Nurses Home, Milford Hospital, Milford. Subject: Acute Anterior Poliomyelitis—Its Diagnosis and Treatment. Instructor: R. Cannon Eley. Joseph Ashkins, *Chairman*.

DEATHS

DAY—CHARLES ORIN DAY, M.D., of Boston, died February 23. He was in his fifty-ninth year.

Born in Williamsburg, he graduated from Yale University in 1903 and received his degree from the Harvard Medical School in 1907. He served internships at the Massachusetts General Hospital and at the Sloane Hospital for Women, New York City. Dr. Day had practiced in Hingham, where he was well known as an obstetrician, before coming to Boston as an ear, nose and throat specialist.

Among his affiliations were fellowships in the American Medical Association and the Massachusetts Medical Society. He was consulting surgeon at the Boston Eye and Ear Infirmary, the Boston Lying-in Hospital, the Florence Crittenton Leagues Hospital and the Brooks Hospital, Brookline. His clubs included the Harvard and Yale clubs of Boston.

A sister, Mrs. Robert Keep, of Farmington, Connecticut, survives him.

DEWING—LOUIS A. DEWING, M.D., of 31 Avon Street, Cambridge, died February 21 at his home. He was in his sixty-sixth year.

Born in California, he attended Harvard University in 1890 and 1891 and studied at Harvard Medical School in 1893 and 1894 before receiving his medical degree at the Medico-Chirurgical College of Pennsylvania.

Dr Dewing was a fellow of the American Medical Association and the Massachusetts Medical Society. His widow and a son survive him.

LOWE—FRED M. LOWE, M.D., of 1354 Washington Street, Newton, died February 28. He was in his eightieth year.

Dr Lowe was born in Lawrence, Kansas, and was graduated from Yale University in 1882 and from the Harvard Medical School in 1885.

For thirty years he was city physician of Newton prior to his retirement in 1935. He was a member of the Newton Hospital staff from 1902 until the time of his retirement. Dr Lowe was a member of the American Medical Association and a fellow of the Massachusetts Medical Society.

Two grandchildren in New York survive him.

QUIMBY—CHARLES M. QUIMBY, M.D., of 38 Pleasant Street, Gloucester, died February 25 at his home. He was in his sixty-ninth year.

A native of Hill, New Hampshire, he graduated from the Maryland Medical College in 1904. He served his internship at the Old Gloucester Hospital.

Dr Quimby was a fellow of the American Medical Association and the Massachusetts Medical Society.

His widow, two sons, three daughters and two sisters survive him.

MISCELLANY

1938 AMERICAN MEDICAL ASSOCIATION MEETING—SAN FRANCISCO

When San Francisco was selected as the host city for the 1938 annual session of the American Medical Association, the profession of this Golden Gate metropolis promptly initiated plans for the comfort, pleasure and entertainment of all who come to that national meeting. A local executive committee on arrangements composed of five members, with Dr Howard Moxrow as general chairman and Dr Frederick C. Warnshuis as general secretary, and eighteen subcommittees have been busy since July in developing plans and local arrangement details. Their objectives are the biggest, best and most memorable annual session in the history of the American Medical Association.

Atlantic City, Kansas City, Cleveland, Detroit, with their known facilities and attractions have been host cities in recent years, and have justified their selection as meeting places. However, and without disparagement, none of them possess the background, the setting, the resources, the history and romance, or the facilities that are found in San Francisco and in the great state of California—the Golden Bear Empire of the Pacific Coast. To reveal these, to extend California's and San Francisco's noted hospitality, and to cause those who plan to attend the 1938 session to experience ten days of profit and pleasure midst the environs of the annual meeting city, is the goal toward which the local profession is pointing.

The Local Committee on Arrangements cordially invites the profession of the country to be San Francisco's guests this coming June. Decide now to attend the 1938 American Medical Association meeting and plan accordingly. During the coming months an insight to some of the feature functions will be disclosed, but the final details and program of events will not be revealed until you arrive. You will long regret it if you fail to attend the coming national meeting. Talk it over tonight with the good wife and your professional associates, and join the party of

your state members that is coming to San Francisco—June 12 to 17, 1938.

NEW ENGLAND OTO-LARYNGOLOGICAL SOCIETY

The following were elected officers of the New England Oto-Laryngological Society at the annual meeting on Wednesday, February 16: president, Dr William Goodell, of Springfield, vice president, Dr Charles D. Knowlton, of Boston, secretary treasurer, Dr Philip E. Meltzer, of Boston, executive committee, Dr Frederick T. Hill, of Waterville, Maine, and Dr Lyman Richards, of Boston.

PHILIP E. MELTZER, M.D.,
Secretary-Treasurer

CORRESPONDENCE

PRACTICE OF OPTOMETRY

To the Editor Enclosed is a transcript of the decision recently handed down by the Supreme Court of Massachusetts relative to certain aspects of the practice of optometry. I believe it will be of interest to readers of the *Journal*.

STEPHEN RUSHMORE, M.D., Secretary,
Board of Registration in Medicine.

State House,
Boston, Mass.

* * *

RAYMOND McMURDO v JOHN R. GETTER et al LUMMUS, J

The Plaintiff, a duly registered optometrist, practicing in Spencer, brought this bill "for his own benefit, for the benefit of other optometrists, and for the benefit of the public" to restrain the Defendants, a firm of opticians in Worcester, not physicians or registered optometrists, from practicing optometry in competition with the Plaintiff and other optometrists without being registered under the statute. Neither duly registered optometrist practicing in Worcester was admitted as an intervening party Plaintiff. The case was reported to us on agreed facts without decision.

No question is made of the right of the Plaintiff and the intervenor to relief if the Defendants are practicing optometry illegally.

The Defendants offer for public sale eyeglasses, including frames and lenses desired, to correct defective vision, upon prescription by physicians and optometrists duly registered as practitioners in this Commonwealth. But almost all the prescriptions actually filled are those issued by a physician employed at a weekly salary by the Defendants in their place of business. A customer who desires eyeglasses is taken to the physician who examines the eyes and prescribes eyeglasses if needed. Other employees of the defendants assist the customers in selecting the shape and style of frames desired, grind and fit the lenses in accordance with the prescription of the physician and then adjust the finished eyeglasses to the eyes of the customer.

We conclude that the physician is the servant of the Defendants, notwithstanding the fact that the Defendants actually exercise no control over the mode, manner or result of the examination of the eyes of the customer, and the doctor is left free to exercise his own will and judgment and to use his own professional skill and methods in making such examination. All questions of price and

business policy are determined by the Defendants. The customer pays nothing except a fixed price for the eye glasses which is the same whether he brings in his own prescription or obtains one from the physician employed by the Defendants. That price is retained in whole by the Defendants.

The Defendants contend that they are not practicing optometry illegally, although they are not registered optometrists and yet reap all the financial reward of a practice conducted by their servant who is a physician, and as such, entitled to practice optometry without registration.

The statute (G. L. [Ter. Ed.] c. 112, pp. 66-73, as amended by St. 1934, c. 339, p. 2) defines the practice of optometry as "the employment of any method or means other than the use of drugs for the diagnosis of any optical defect, deficiency or deformity of the human eye, or visual or muscular anomaly of the visual system, or the adaptation or prescribing of lenses, prisms or ocular exercises for the correction, relief or aid of the visual functions." (P. 66.) Before being registered as an optometrist, a person must possess certain educational qualifications and must pass an examination. (P. 66.) Whoever, not being lawfully authorized to practice optometry, practices optometry, or holds himself out as a practitioner or, or as being able to practice, optometry, or violates any other provision of (pp. 66-73, inclusive), or any rule or regulation made under authority thereof, is punishable criminally. (P. 72a.) The restrictions of the statute shall not apply to physicians and surgeons lawfully entitled to practice medicine in the Commonwealth, nor to persons who merely fill prescriptions, or sell eyeglasses as merchandise from permanently located and established places of business without the purpose of correcting defective vision. (P. 73.) Two other exceptions are mentioned later in this opinion. See also St. 1937, c. 287, which takes effect on January 1, 1938.

The Fourteenth Amendment to the Federal Constitution and Articles 1, 10, and 12 of the Declaration of Rights of the Constitution of this Commonwealth, protect every person in the enjoyment of his liberty and property. With in those words is included the right to engage in any lawful occupation, at least any not affected with a public interest. But that right, like many others, may be qualified or restricted under the police power, never precisely delimited, to take rational action for the protection of the public safety, health, morals, comfort and good order. Where the interests of the public might be endangered by the activities of incompetent or unreliable persons, one may be required to show his qualifications before engaging in any particular occupation and to obtain a license attesting his skill and character.

The requirement of license or permit engaging in practice has been held constitutional as to physicians.

Sometimes a statute has purported to require on the part of the proprietor of a business a license attesting skill in acts which he does not perform, but causes to be performed on his behalf by a duly qualified and licensed servant. In *Louis K. Liggett Co. v. Baldridge*, 278 U. S. 105, a statute of Pennsylvania forbade a partnership or corporation to operate a pharmacy unless all the partners or stockholders were licensed pharmacists. It was held that the requirement of ownership by registered pharmacists had no legitimate relation to the health or interests of the public, and that the statute deprived the corporation of its property without due process of law. Such instances are to be distinguished from those in which, for sufficient reason, a license has been required from the proprietor of a business, attesting his fitness to carry it on.

A different rule has been applied to the learned professions. These are characterized by the need of unusual

learning, the existence of confidential relations, the adherence to a standard of ethics higher than that of the market place, and in a profession like that of medicine by intimate and delicate personal ministrations. Traditionally, the learned professions were theology, law and medicine, but some other occupations have climbed, and still others may climb, to the professional plane. Dentistry, a branch of medicine, has done so within modern times. Professional men may be held to a higher ethical code, for example by the restriction of advertising, than men engaged in ordinary business.

The rule is generally recognized that a licensed practitioner of a profession may not lawfully practice his profession among the public as the servant of an unlicensed person or a corporation, and that, if he does so, the unlicensed person or corporation employing him, is guilty of practicing that profession without a license. A corporation as such, cannot possess the personal qualities required of a practitioner of a profession. Its servants, though professionally trained and duly licensed to practice, owe their primary allegiance and obedience to their employer rather than to the clients or patients of their employer. The rule stated recognizes the necessity of immediate and unbroken relation between a professional man and those who engage his services. It was applied recently in this Commonwealth in the case of lawyers. The judicial branch of government to which is entrusted the regulation of practice by attorneys at law, has never relaxed the rule. In the absence of statutory modification in favor of hospitals or others, the same rule applies to physicians and dentists. The position of a physician normally is not that of a servant of anyone.

As to optometrists, there seems to be a conflict of authority. Undoubtedly the fitting and sale of eyeglasses began as a trade and not as a profession. There is some support in decided cases for the proposition that it must remain a trade, in which an unlicensed person or a corporation may engage, provided the actual work is done by a skilled servant duly licensed.

The consideration to the contrary seems to us more weighty. In recent years abnormalities of the eye, like those of the teeth, have been found sometimes, to indicate and often to result in serious impairment of general health. The work of an optometrist approaches, though it may not quite reach, ophthalmology. The learning and the ethical standards required for that work, and the trust and confidence reposed in optometrists by those who employ them, cannot be dismissed as negligible or as not transcending the requirements of an ordinary trade. We cannot pronounce arbitrary or irrational the placing of optometry on a professional basis. This conclusion finds support in other jurisdictions.

Although the statute does not show an uncompromising determination to apply purely professional standards to optometrists, we think that they are in effect placed on a professional plane. A certificate of registration may be revoked for unprofessional conduct. (p. 71), although the statute speaks of an optometric practice in business.

The general principle is recognized that there should be direct professional relations between an optometrist and the members of the public who engage his services. Sec. 72 declares that no optometric practice or business

shall be conducted under any name other than that of the optometrist or optometrists actually conducting such practice or business. That provision, unless this case falls within some exception to it, makes illegal what was done in this case. It prohibits, as a general rule, the practice of optometry by a layman or a corporation through servants, who are registered optometrists. The exceptions tend to show the existence of the general rule for if the

rule were not recognized, the exceptions need not have been expressed. One exception related to the continuance of an optometric practice by the unregistered spouse of a registered practitioner (P 73). Another is that the statute shall not 'prevent the employment by any person of a registered optometrist to be in charge of, or practice optometry in, an optical department conducted by such a person' (P 73). The servant employed in this case did not come within the exception, for he was a physician, not a registered optometrist. It is true that a physician may practice optometry (P 73). But when it comes to the practice of optometry as the servant of a layman or a corporation, the Legislature may rationally have thought that a physician who would accept employment in an optical department would not be likely to acquire a registered optometrist (P 73). We think that upon the agreed facts, that Defendants are practicing optometry without right.

On the agreed facts there must be a decree restraining the Defendants, from practicing optometry, either personally or by any servant or employee, unless and until, and then only to the extent that, they shall become lawfully entitled to do so, with costs against them.

Ordered accordingly

COMPULSORY SEROLOGIC TESTS BEFORE MARRIAGE

To the Editor In a debate held on the evening of January 20 at Ford Hall between Dr Stanley Osborn, health commissioner of Connecticut, and Dr Nels Nelson, director of the Division of Communicable Diseases, Massachusetts Department of Public Health, some statements were made by Dr Nelson which are of a very serious nature. Since I am interested in House Bill 669, which deals with compulsory blood tests before marriage, I believe it is up to me to bring this matter into the open.

It seems to me that Dr Nelson has become obsessed in some way over the blood test. Dr Nelson said that blood tests have no value in communicable diseases and that they run about 50 per cent efficient. He discussed at length the value of the various blood tests and said that blood tests were of no value until about four weeks after the primary lesions appeared. This before a body of doctors or laboratory men and technicians would be an excellent discourse but not before the lay public. One lady representing an organization interested in social diseases spoke and said that she was upset and did not know just where she stood on this question. She had always believed that blood tests were of paramount importance in discovering syphilis, but from what she heard from Dr Nelson it looked as if they were of little value, for he said that some individuals would have a positive test and yet would not have syphilis and others with a negative test would have syphilis. He also said that some individuals contracting syphilis have no treatment of any kind and yet are unable to transmit the disease.

I talked to about a dozen individuals who attended this meeting, and they seemed to be of the opinion that a blood test was not so important as they had thought, notwithstanding the fact that, after being called upon by Dr Gilbert Smith, I said in part that Dr Nelson did not intend to convey the opinion that blood tests were of no value and should be thrown overboard. They are of value. We have used them successfully and relied upon them since they were first brought out. When a report comes back positive I first check up on the symptoms presented by the patient and have a test made at another laboratory, if the latter is positive, the patient is advised to start immediate treatment.

If Dr Nelson could suggest a blood test that is more efficient than our present ones, his criticism would be quite all right, but as I know he has none, it is of the utmost importance that he curtail his remarks, at least before the lay public.

H M LANDESMAN, MD

366 Commonwealth Avenue,
Boston.

* * *

The Commonwealth of Massachusetts
Department of Public Health
State House, Boston

February 7, 1938

A copy of Dr Landesman's letter was submitted to Dr Nelson, whose reply follows

To the Editor Dr H M. Landesman in a letter to the editor of the *New England Journal of Medicine* seeks to bring into the open 'a matter which is already so much in the open that it was a subject of public debate on the evening of January 20 at Ford Hall, and of review at a public hearing on January 27 before a joint legislative committee on public health.

I did discuss blood tests for syphilis at Ford Hall and I did discuss blood tests for syphilis before the joint legislative committee in connection with this department's objection to compulsory blood tests before marriage. Dr Landesman's report of my statements, however, are so at variance with the facts that to review all his errors in reporting would consume too much valuable space. I refer Dr Landesman to my various publications and to those of this department which have to do with the control of syphilis and which have appeared in the *New England Journal of Medicine* and elsewhere at relatively frequent intervals during the past ten years. I refer him particularly to the discussion of blood tests by Garfield and Nelson in the *New England Journal of Medicine* (209 1016-1017, 1933). I will also call his attention to the three or four reports of the United States Public Health Service which have appeared in the *Journal of the American Medical Association*, the *American Journal of Public Health* and *Venerical Disease Information* and which are concerned with evaluations of serologic tests as performed in state and city laboratories.

I do not claim to be a serologist, but I do claim to have a better understanding of the value of blood tests, by themselves, in the diagnosis and control of syphilis, than I am given credit for in Dr Landesman's report of my discussion of them. No one who knows anything about syphilis will deny the value of blood tests. On the other hand, neither will anyone who knows anything about syphilis close his eyes to the limitations of blood tests, alone, in the diagnosis of syphilis.

What seriously concerns me is Dr Landesman's apparent belief that people should be compelled to have blood tests before marriage but should not be informed at all as to the significance of blood tests. One reason among many for our opposition to compulsory blood tests is that a blood test law would tend to support the public in its erroneous belief that a negative blood test rules out infection with syphilis and that a positive blood test indicates communicable syphilis.

The Illinois law is a perfect example of the foolish action which may be taken as the result of misunderstanding of this point. The American public has just recently discovered that syphilis is a prevalent disease and a menace to public health. The people have, furthermore, been put under terrific pressure to do something for the control of syphilis. Unfortunately, action too often finds

expression in compulsory laws. Action of this sort is bound to be ill advised when it is stimulated almost wholly by emotion rather than by any sound knowledge of the problem.

If the American people are to understand syphilis, it is inconceivable that they should be kept in the dark concerning the nature, significance and limitations of blood tests for syphilis. Blood tests are negative throughout the entire incubation period of syphilis. They may be negative for from three to four days to as long as three weeks or more, after the appearance of the primary lesion. They may be negative after a little, but entirely inadequate treatment. They may remain forever positive in those who have had adequate treatment, and they have no significance whatsoever in terms of the communicability of syphilis.

Patients with communicable syphilis may have negative blood tests and should not be permitted to marry. Many patients with positive blood tests have non-communicable syphilis and, under proper conditions, should be permitted to marry. Nothing less than a truthful history, a full and competent physical examination, plus whatever evidence may be had from blood tests performed in a reliable laboratory, will suffice to rule out communicable syphilis.

Blood-test-before marriage laws imply that the public may rest secure on the evidence offered by the blood test alone. Although the Wassermann Laboratory of this department performs a test which stood at the top in the recent evaluation of blood tests (over 90 per cent sensitive and 100 per cent specific), many laboratories fail to detect syphilis in from 40 to 50 per cent of the cases. There are hundreds of laboratories in this country performing blood tests which have never been evaluated by anybody.

I repeat, that if the public is to be compelled to have blood tests performed before marriage, the public should fully understand the nature, significance and limitations of blood tests.

N. A. NELSON, M.D., *Director*
Division of Genitoinfectious Diseases.

Massachusetts Department of Public Health,
State House, Boston.

BUT IT CAN HAPPEN AGAIN!

To the Editor While doing an exploratory of the supraclavicular regions of a grandchild's big doll, born in a New England shop at least seventy five years ago I came upon the lower corners of two pages of some Boston newspaper published about the first of November 1862, which had been used as part of the stuffing of the pseudolady's body. The yellowed and closely printed paper, although not over two square feet in size area including both sides, bore at least eight or nine medicine advertisements.

I read these with interest sufficient to assure me that members of the profession, if not others, in Massachusetts and elsewhere might also read them with average mental satisfaction. The thought that the very large majority of the *Journals*' readers cannot recall the time when state ments as false as those contained in these advertisements were unforbidden by custom or any law confirmed my intention. The few readers who do remember these features of the peaceful and easy horse-and-buggy days perhaps will get out of them enough of amusement and of

psychological gratification to warrant their reproduction in the *Journal*. They certainly contain humor, and there is minor evidence in concrete form of how greatly the art and science of medicine have advanced even in a generation or two. The sixues, if I mistake not, exhibited the extreme development of the characteristically American habits of hustle and of raucous competition, begun long before the Civil War, this type of advertising was ended only by the might of well-enforced law and an awakened common conscience—or shame. Here are some of the advertisements, verbatim.

DR. BIRMINGHAM
NATIVE INDIAN PHYSICIAN
OFFICE, 63 CAMBRIDGE ST. BOSTON
(Corner Chambers street)

MONDAYS TUESDAYS and WEDNESDAYS from 9 A.M. to 2 P.M.
Store open from 8 A.M. to 6 P.M.
A BALM FOR EVERY WOUND

Dr. B. warrants his med. ine to operate as may be necessary and not deplete the system and at the same time to give a healthy tone to the digestive organs, and regulate the nervous system. This medicine has not been compounded from any new discovery but from a knowledge of the Indian method as practiced for many centuries and a practical evidence of physical anatomy which enables the Doctor to prescribe in safety in all cases.

Dr. B. has medicines which he not only prescribes in all chronic diseases but which he warrants will effect a cure when hope has departed. The Doctor's extraordinary natural powers to make an accurate examination of any disease to which human flesh is heir has astonished thousands in this city and elsewhere, and he feels assured that those who entrust themselves to his care will not have cause to regret it. Examinations gratis every day in the week excepting Thursday, Friday and Saturday when he may be found at his residence, on Tanner street, junction of Ayres New City and Lowell E. R. Lowell

DR. WILLIAM CLARK'S

ANTI SCROFULA PANACEA

Cures Fever and Ague Jaundice Rheumatism Pulmonary Affections, and Scrofula and Humors. The GENUINE manufacture ONLY by
FRANKLIN PUTNAM
No. 4 Newbury place.

DR. TOBIAS VENETIAN LINIMENT

An instantaneous remedy for chronic rheumatism headache, toothache, croup, colic, quinsy, sore throat and pains in any part of the body. Try a bottle and be convinced. Remember this article is a success, not an experiment—for 14 years it has been tested. Every one who uses it recommends it. No medicine ever had such a reputation as this liniment. It has worked its way before the public and all are loud in its praise. Chronic rheumatism. Thousands who laid for weeks on a bed of agony and never walked without the aid of crutches with this complaint can testify to the magical effects of this liniment. They are cured, and proclaim its virtues throughout the land. Remember relief is certain and a positive cure is sure to follow. Headache of all kinds we warrant to cure. Purged sore throat, quinsy and diphtheria are robbed of their terrors by a timely use of the Venetian Liniment. It has saved hundreds the past three months.

Price 25 and 50 cents a bottle. Depot No. 56 Cortlandt street New York. Sold by all Druggists. Wholesale by GEO. C. GOODWIN & CO. 11 & 12 Marshall street Boston.

FACTS FOR SOLDIERS

Throughout the Indian and Crimean Campaigns the only medicines which proved themselves able to cure the worst cases of Dysentery, Scoury and Fever were HOLLOWAY'S PILLS and OINTMENT. Therefore, let every Volunteer see that he is supplied with them. Only 25 cents per pot or box.

VICTIMS OF CATARRH

Will please bear in mind that Dr. Wadsworth's celebrated DR. UP will cure them of that complaint after all the extravagantly vaunted nostrums have failed though the case be never so bad. For sale by M. S. BLISS & CO. and G. C. GOODWIN & CO.

Also by the Proprietor H. H. BURLINGTON Providence R. I.

IT FALLS ALIKE TO THE JUST AS WELL AS THE UNJUST—The scourge of Monthly Sufferings, so common to Females, remains as mysterious in the works of the Creator. No direct relief has been found for it until the application of *Hunnewell's Cold Anodyne* which has given astonishing relief in all cases, while Nature's end is not disturbed. To those who dread the periods of so much suffering the nervous system sympathizes, a wreck follows, and all the weakness and debility so common to women date from it. For all nervous and spasmodic complaints the anodyne is truly invaluable and should be in every family.

Also in cases of *Throat and Ling Complaints* let HUNNEWELL'S UNIVERSAL COUGH REMEDY have the confidence of all and to test the

rule were not recognized, the exceptions need not have been expressed. One exception related to the continuance of an optometric practice by the unregistered spouse of a registered practitioner (P 73). Another is that the statute shall not "prevent the employment by any person of a registered optometrist to be in charge of, or practice optometry in, an optical department conducted by such a person (P 73). The servant employed in this case did not come within the exception, for he was a physician, not a registered optometrist. It is true that a physician may practice optometry (P 73). But when it comes to the practice of optometry as the servant of a layman or a corporation, the Legislature may rationally have thought that a physician who would accept employment in an optical department would not be likely to acquire a registered optometrist. (P 73) We think that upon the agreed facts, that Defendants are practicing optometry without right.

On the agreed facts there must be a decree restraining the Defendants, from practicing optometry, either personally or by any servant or employee, unless and until, and then only to the extent that, they shall become lawfully entitled to do so, with costs against them.

The Illinois law is a perfect example of the foolish action which may be taken as the result of misunderstanding of this point. The American public has just recently discovered that syphilis is a prevalent disease and a menace to public health. The people have, furthermore, been put under terrific pressure to do something for the control of syphilis. Unfortunately, action too often finds

NOTICES

Vol. 218 No. 9

pause It is an involutonal change, and although the disease may start with a solitary cyst, other cysts may develop in the same or contralateral breast. The cyst has a smooth, spherical outline and transmits light. The content of the cyst, which is frequently called 'blue-domed' is a light milky fluid. If the diagnosis is uncertain, exploration should be done. Otherwise the cysts should be aspirated and endocrine therapy carried out.

There were 610 cases of fibroadenoma—a benign tumor. The average age at which women present themselves with this lesion is 25 years. The average duration of symptoms is from 3 to 5 years. Examination reveals a well-developed breast. The tumor is solitary, dense and has a lobulated surface. There is no dimpling of skin or atrophy of overlying fat. Histologically the tumor represents an overgrowth of connective tissue with hypertrophy of the ducts. The tumor may double its size during pregnancy. Rarely the tumor may become malignant, particularly at the menopause. It should be removed surgically at the time of diagnosis.

There were 182 cases of benign intracystic papilloma in the series. This is a tumor arising from embryonic rests, it is found near the nipple and becomes manifest at the menopause. The outstanding symptom is bloody discharge from the nipple. At times this tumor may be transformed into a carcinoma. Should this occur, the degree of malignancy is low grade. Operative intervention for benign intracystic papilloma should be postponed till the tumor becomes palpable, in the interim the patient is watched very closely.

In the carcinoma group there were 2700 cases, of which 2100 have been classified. These are divided into three groups. The first group consists of half the cases. This is the scirrhous carcinoma, or carcinoma simplex. Most of the cases appear between 40 and 50 years of age. The characteristic features are it is solitary, it appears very near the examining finger because of the atrophy of the overlying fat, its consistence is hard, its shape irregular, and it is fixed to neighboring structures, as the skin. Fifty per cent of the cases in this group had axillary lymph node metastases at the time of treatment. The average duration of symptoms was from 6 to 12 months. There were 5-year survivals in 29 per cent of the cases. As a group, it is a situation which needs considerable improvement.

One quarter of the carcinoma group was made up of papillary carcinomas. This is the most favorable type of cancer, and has 60 per cent 5-year survivals. In the remaining quarter the prognosis is very poor, these cases chiefly consist of local recurrences following operation and of huge tumors involving the whole breast.

Dr Reuben Davidoff opened the discussion, stressing the need for therapeutic improvement. He suggested radiation as a possible answer to the problem. Dr Harry Friedman presented photomicrographs revealing the effect of x-ray irradiation on 2 cases of carcinoma of the breast. An increase in fibrous tissue was a prominent feature. Dr Max Ritvo presented slides of soft tissue roentgenograms revealing the outlines of breast tumors. He suggested castration in cases of carcinoma as a preventive of pregnancy in order to prevent increased growth imparted to the tumor by this state. He also advised x-ray irradiation to the supraclavicular area and axilla after radical operation. Dr Carl Bearse stressed the importance of early treatment of mammary carcinoma.

In closing the discussion, Dr Geschickter stated that in the last two decades the 5-year survivals at the Johns Hopkins Hospital have increased 5 per cent.

BROOKFIELD MEDICAL CLUB

The Brookfield Medical Club held its 557th meeting at Ye Olde Tavern, West Brookfield, on February 16, with Dr Joseph Slowick, of Palmer, as host. Dr James Kilburn, of Springfield, delivered the address of the afternoon on the subject of 'Malignant Tumors of the Kidney' At this meeting a larger number of members attended than at any other regular meeting in the history of the club, 28 out of 36 members being present. Dr Raoul J LeBeau, of Spencer, was elected to membership at this meeting

The March meeting will be held at the Phoenix Restaurant, Ware, on March 16, with Dr Tracy L. Roberson, host, and Dr George L. Schadt, of Springfield, as speaker, the latter's subject will be Modern Laboratory Technique for the Practicing Physician

J R. FOWLER, M.D., Secretary

GREATER BOSTON MEDICAL SOCIETY

The Greater Boston Medical Society met February 1 in the auditorium of the Beth Israel Hospital, Boston. The chairman was Dr Kermit C Rosen, and the speaker Dr Charles Geschickter, of Baltimore. His subject was 'Diagnosis and Treatment of Neoplasms of the Breast.' The material presented came from the cases of the Johns Hopkins Hospital

In the benign group there were 2021 cases. Of these 75 were cases of benign hypertrophy. This lesion is fundamentally an overgrowth of fibrous tissue—peculiarly abundant in the human breast. The commonest period of manifestation of this condition is at puberty, although occasional cases appear after the first child is born. The condition is not precancerous. Its greatest harm is the mental effect on the patient. Since plastic operations are usually unsatisfactory, the operation, if performed, should be mastectomy. Estrin therapy is unsatisfactory and usually aggravates the condition.

Chronic cystic mastitis yielded 1129 cases, which were divided into three groups: mazoplasia (painful breast), 387 cases, adenosis, 172 cases, and cystic disease, 570 cases. In all its forms it is an endocrine disturbance.

Mazoplasia appears early in life, the usual age being 30 years. The patients are single or married, but sterile. The menstrual cycles are normal. The breasts may be painful throughout the cycle. Examination reveals a firm upper outer quadrant to the breast. The breast becomes reduced in size after the menstrual period. Good therapeutic results are obtained with estrin and with assurance.

Adenosis, or Schummelbusch's disease, is found most commonly in women between 38 and 42 years of age. They are of the nervous type, the thyroid is frequently palpable, and the menstrual cycle is short, lasting from 24 to 26 days. The lesions are frequently bilateral. There is a nodular or shotty feel in the upper outer quadrant and about the periphery of the breast. There may be cysts, which as a rule are small. Microscopically there is an overgrowth of fibrous tissue and glands. The latter situation is at times mistaken for cancer. Evidence does not indicate that chronic cystic mastitis is a precancerous lesion.

Cystic disease is the third form of chronic cystic mastitis. It appears most commonly at the time of the men-

BOOK REVIEWS

Chemistry of the Brain Irvine H. Page. 444 pp. Springfield and Baltimore Charles C Thomas, 1937 \$7.50

The study of the chemistry of the brain is of fairly recent origin and, as Dr Page points out in his introductory chapter, the founder of this branch of medicine, J. L. W. Thudichum, did his work in the last half of the nineteenth century. A man of wide culture, living in London, Thudichum's report for the Privy Council has only recently been re-read and evaluated. He was able to determine the structure of many substances in the brain and his classical work, *Chemical Constitution of the Brain* (1884), was the only monograph on the subject, up to his time, of any importance.

Dr Page has carried on this work, so ably begun by Thudichum and more recently promulgated by the chemical division of the Kaiser Wilhelm Institute in Munich, at the Rockefeller Institute for Medical Research in New York City. The author of this monograph not only includes what is ordinarily considered the chemistry of the brain substance, but has extended his study to the chemistry of the blood as it enters and leaves the skull, of the cerebrospinal fluid, of brain dysfunction and also of tissue culture. The book brings together a widely scattered literature in a form which is easy to refer to, for the text is particularly well set up and the immediate references are found as footnotes. Although the book cannot be completely analyzed in this review, a list of the chapters will indicate its scope: 'Sterols, Phosphatides, Fatty Acid Metabolism,' 'Nitrogenous Metabolism, Electrolytes and Gases,' 'Enzymes of the Brain,' 'Diet, Vitamins and Degeneration of the Nervous System.' Each of these sections and others are carefully reviewed. The book closes with an interesting philosophic chapter on 'The Brain and Thought.' This monograph supplants all previous works in this highly technical field. Its publication forms an epoch in brain chemistry.

In addition to the contents of this book, one notes with pleasure the easy reading page, the excellent charts and diagrams, the lightweight paper, and other features of bookmaking, which serve to classify this volume at the very top of recent scientific publications.

Twenty-Five Years of Health Progress A study of the mortality experience among the industrial policy-holders of the Metropolitan Life Insurance Company 1911 to 1935 Louis I. Dublin and Alfred J. Lotka. 611 pp. New York Metropolitan Life Insurance Company, 1937

Most valuable source material has been made available by the Metropolitan Life Insurance Company in this volume. The authors state in the preface: 'The body of facts given here may serve as a guide to the formulation of a working program, the data will reveal the best points of attack and make possible the concentration of effort where

it will yield the most good. Throughout the volume are indications of what yet remains to be accomplished in the prevention of sickness and premature death. To this end investigators interested in extending the boundaries of medical knowledge will find in the pages which follow many suggestions for further research.'

The book should be of great value to individuals studying the trends of disease. In doing this, however, one should bear in mind that the group studied is not a cross-section of the American populace. It differs considerably in economic status, in age and sex distribution, in color and in occupation. To the individual who keeps these facts in mind, this book offers most excellent source material, and the reputation of its authors is such that it may be used with no reservations aside from those mentioned above.

This volume covers general mortality from all causes, trend of longevity through a quarter of a century, the principal communicable diseases of childhood, tuberculosis, influenza and pneumonia, cancer, principal cardiovascular renal diseases, diabetes mellitus, diseases of the puerperal state, typhoid fever, acute poliomyelitis, syphilis, acute rheumatic fever, exophthalmic goiter, pernicious anemia, ulcer of the stomach and duodenum, diarrhea and enteritis, appendicitis, hernia, intestinal obstruction, cirrhosis of the liver, biliary calculi, suicide, homicide and various forms of accidents.

The volume is addressed to physicians, health officers, sociologists, life insurance officials and others interested in the health and welfare of the wage-earning population.

The general usefulness of this book will naturally be limited to students and authors of medical statistics, particularly those statistics dealing with trends of disease.

The chapter on methods of compilation and analysis should be of great help to writers, the tables and graphs which are scattered throughout the text, as well as in the sixty-four page appendix, should be advantageous. Many of the tables are based on rates standardized for age. This removes the pitfall of crude rates. For example, cancer among white females when standardized showed no increase throughout the entire period although the crude rates for the same period showed a considerable rise.

The book should admirably serve the purpose for which it was written.

The Human Mind Karl A. Menninger. Second edition. 504 pp. New York Alfred A. Knopf, 1937 \$5.00

When the first edition of this work appeared, it represented a happy compromise between those books dealing with psychologic phenomena which tacitly suggest to the lay reader that he is being allowed in on the ground floor to see revealed the secrets of the physician and psychiatrist and those other books discussing the basic phenomena of psychiatry which are in themselves scholarly but none the less puzzling even to psychiatrists long past the tyro stage. In this volume, the author has with Aristotelian logic, presented the field of personality and described the form, etiology and treatment of the major psychiatric conditions. Illustration is for the most part case material from Dr Menninger's extensive and varied experience in mental disease which began with his training at the Harvard Medical School and the Boston Psychopathic Hospital under the late Dr E. E. Southard and has continued until the present time. (He is now co-director of the Kansas sanatorium bearing his surname.) An acknowledgment is made in the reprinted preface to the author's teachers: this includes such outstanding names as Southard, Meyer, Jelliffe, White, Healy and Williams.

THE GUILD OF ST LUKE

The regular meeting of the Guild of St. Luke will be held at the Boston Medical Library, 8 Fenway, on Monday evening, March 7, at 8 15

Dr Morris Fishbein, editor of the *Journal of the American Medical Association*, will speak on 'Medicine and the National Policy' Collation will follow

NUMBER 10

THE MASSACHUSETTS PNEUMONIA PROGRAM

HENRY D CHADWICK, M.D *

BOSTON

THE Massachusetts records of vital statistics for the past eighty years show that pneumonia has been one of the six leading causes of death in every age group from infancy to old age for that entire period. The rate for each decade beginning with 1856-1865 rose from 107.4 per 100,000 to a maximum of 180.7 in 1886-1895, and has since declined to its present level of 96.1. This is but 11 points, or 10.3 per cent, lower than it was eighty years ago, but compared with the highest rate, which was recorded forty years ago, the decline has been 84.4 points, or 51.7 per cent.

at least do something about it. With the aid of Dr. Benjamin White, director of the Antitoxin and Vaccine Laboratory, he developed a plan that was put into effect in January, 1931, and has been carried out since then with but few modifications.

The Massachusetts pneumonia study had two objectives: the evaluation of pneumonia serum under the conditions of the general practice of medicine, and the development of plans for the distribution of this serum for the treatment of those patients who might reasonably be expected to benefit from its use. It thus embraced prob-

Table 1 *Average Annual Death Rates per 100,000 Population of Certain Communicable Diseases in Massachusetts*

YEARS	PNEUMONIA (ALL FORMS)	TUBERCULOSIS (ALL FORMS)	WHOOPING COUGH	MEASLES	SCARLET FEVER	DIPHTHERIA	TYPHOID FEVER	SMALLPOX
1856-1865	107.4	446.4	23.8	17.1	101.3	86.1	92.5	11.0
1866-1875	132.2	401.2	20.7	15.1	76.6	58.4	80.8	17.3
1876-1885	150.1	378.3	15.1	9.6	33.8	127.2	47.4	1.3
1886-1895	180.7	326.8	12.8	8.7	20.6	73.7	36.9	0.3
1896-1905	174.7	242.9	10.3	7.3	9.9	38.4	21.0	1.6
1906-1915	174.1	170.5	8.2	6.4	6.9	19.4	10.6	0.1
1916-1925	164.8	113.7	9.3	7.8	3.7	15.2	2.9	0.06
1926-1935	99.1	62.8	3.7	3.0	2.4	3.8	0.8	0.002
1936	96.3	43.1	1.2	0.8	1.0	0.6	0.2	0.000
Percentage decline 1856-1936	10.3	90.3	94.9	95.3	99.0	99.3	99.8	100.0

All the other communicable diseases with which the Massachusetts Department of Public Health has been chiefly concerned, declined from 90 to 100 per cent in the same period of time. Tuberculosis, which had formerly had a rate four times as high as that of pneumonia, declined to less than one half of it. Both these diseases claimed a large percentage of their victims when they were in the prime of life and of the greatest economic value to the community. Public-health authorities made great efforts to control and eradicate tuberculosis, but kept only a tally sheet of the deaths from pneumonia. One of the greatest public-health problems was being neglected. Dr. George H. Bigelow, when commissioner of public health, had the foresight and vision to attempt to solve it or

lems of scientific research as well as of administrative procedure.

The purposes of the plan may be summarized as follows:

- 1 To study the epidemiology of lobar pneumonia in the State.
- 2 To promote more prompt diagnosis of the disease.
- 3 To encourage and facilitate earlier and more general serum treatment.
- 4 To study and improve methods for serum production.
- 5 To correlate the studies on serum production with the results following its clinical use.
- 6 To devise procedures for the future prevention, serum treatment and control of the disease.

The development of such a program, looking forward to the eventual state-wide distribution of

Read before a meeting of the American Clinical and Climatological Association, Baltimore, Maryland, October 11, 1937.
Massachusetts Commissioner of Public Health

The purpose of this revision is to evaluate anew the present-day knowledge of the human mind in light of the seven years' advances since the book was first published and of the writer's increasing experience and acquaintance with psychologic phenomena. The attitude of physicians is being directed more and more toward the psychosomatic problem, and due stress is laid upon this point of view. New methods of treating psychoses and neuroses have made necessary the enlargement of the chapter on therapy.

The section dealing with psychoanalysis has been handled with a great deal of delicacy but without undue concession to the antipodal points of view which surround this technique. It is also much more specific than was the same section in the earlier edition, due in large measure to the systematized form of this edition and the arrangement of material.

Dr Menninger's unwillingness to accept the doctrine of "hereditary damnation" has led him to expand on the fruitful possibilities of education by the application of psychologic methods in pastoral work. The importance of trained psychiatric nursing is observed, and it is indicated why an indifferent and untrained nursing personnel has in the past retarded and prevented improvement in many cases of mental disease.

Although this cannot be recommended as a textbook in pure psychiatry for medical students or interns, it can be used as supplementary material by them. It will find its best application as a book to be placed in the hands of physicians in other specialties who find that psychiatric problems interject themselves into a disease syndrome with persistent regularity. Nurses and social workers will waste no time if they make a careful study of its pages. To a certain extent it can be recommended to the relatives of patients who, never having been required to face the problem of mental disease, are resistant to the suggestions of the psychiatrist because they do not know what he is talking about. When the facts are explained as Menninger has done with an economy of space, relatives often become increasingly co-operative to what has previously seemed a bizarre plan of treatment. The author is to be congratulated upon the accuracy, format and diction of this book.

Methods of Treatment Logan Clendening Sixth edition
879 pp St. Louis The C V Mosby Company, 1937
\$10.00

The popularity of this book as demonstrated by the fact that this is the sixth edition cannot be dismissed in figuring its value. To the reviewer the impression is created that an attempt has been made to cover more ground than is possible in such a volume. A great number of procedures are mentioned without making it clear which of the various procedures are universally or in the author's opinion considered more worth while. Some of the methods mentioned in the line of treatment are considered by the reviewer to be of very little value. Therefore, although the student or physician will probably find in this volume a statement in regard to almost any type of therapeutic procedure, he will find some which are not of recognized therapeutic value at the present time and will not receive guidance in regard to which are of more value. In the treatment of congestive heart failure for instance there is no clear-cut or concise statement in regard to just what to do in order to clear up the edema, although there is a considerable amount of space used in a rambling discussion of the pathologic physiology of heart failure. The reviewer is surprised that a book of this type has obtained the popularity to make it worth while for the publishers to put out six editions.

Les Hepatites Maurice Loeper 262 pp Paris Masson et Cie, 1937 60 Fr fr

This little monograph is a summary of our present knowledge of hepatitis due to various causes. The author, besides discussing the causes of abdominal meteorism, ventures the theory that it is due to insufficient circulation to the liver. It must be confessed that his arguments seem quite weak. There is an interesting chapter on catarrhal jaundice and a good chapter on spirochetal jaundice. The discussion of hemachromatosis appears inadequate as there is no reference to the theory of copper poisoning as an etiologic factor. The final chapter, devoted to tuberculous peritonitis as a complication of chronic hepatitis, could have been omitted without damage to the volume. There are numerous illustrations, and the photographs and photomicrographs in the first part of the book are printed upon heavy glazed paper of excellent quality. In the latter part, however, a dull paper is used, which gives the reproductions a muddy appearance. Although this is not a complete treatise, the author has given a fairly good survey of the subject, but more than this, one must commend him for inserting a few references—an unusual and praiseworthy action by a French author.

A Textbook of the Practice of Medicine Oxford Medical Publications Edited by Frederick W Price. Fifth edition. 2038 pp New York Oxford University Press, 1937 \$12.50

This textbook contains 2000 pages of rather finely printed information concerning all phases of the practice of medicine, edited by Frederick W Price and contributed to by a score or more of his colleagues. It represents the best thought in British medicine. Each section is signed by its author or authors and most of the material in this, the fifth, edition has been brought up to date.

Protamine insulin is mentioned as is "sulphon amide," and in most subjects the material is as up-to-date as one could reasonably expect in a work of this scope. Considerable space now devoted to polygraphic tracings of the heart and their significance might well be eliminated in favor of a discussion of the Lead 4 in the chapter on clinical electrocardiography. It was only in these chapters that the reviewer felt that this fifth edition might be lagging behind the times.

It is an extremely useful book for medical students and the editor's hope that it "may be considered a credit to the London School of Medicine" is abundantly fulfilled.

Muir's Bacteriological Atlas C E. van Rooyen. 90 pp. Second edition. Baltimore William Wood & Co., 1937 \$5.25

The first edition of this small book was published by the late Richard Muir in 1927, and consisted of some fifty-odd, excellent, colored plates, with explanatory legends, which were reproductions of charts drawn by Dr Muir and used by him for teaching bacteriology in the University of Edinburgh.

The present edition has been enlarged and the text rewritten by Dr C. E. van Rooyen. Twenty six new colored plates have been added, and the illustrated micro-organisms include not only bacteria but also fungi, viruses, rickettsias and animal parasites. The accompanying legends are short but adequate. The atlas should prove to be extremely valuable to those beginning the study of medical bacteriology. As suggested by the author of this revised edition, it should be used only in conjunction with a standard textbook.

able on an equal basis to all physicians in the State.

Early in the study the State was divided into areas, and two or more locally prominent physicians were selected as collaborators in each area. These men were given a few weeks' time to become familiar with recent literature on pneumonia and were then requested to attend a graduate course on pneumonia arranged through the Harvard Medical School. Laboratory technicians in one or more centrally located hospitals of each area were given a week's training in the State bacteriological laboratory in pneumococcus typing. Concentrated bivalent Type I and Type II anti-pneumococcic serum was supplied only to the collaborators in the special districts, for use in cases of lobar pneumonia which they might see in consultation or in their own practice.

By 1934 a review of the experience of the State bacteriological laboratory with the then new Neufeld method of typing showed it to be simple, rapid and reliable. The time required for typing was reduced in most instances from many hours to a few minutes. During the study, typing was carried out on nearly ten thousand specimens obtained from patients with lobar pneumonia or bronchopneumonia, and in a few instances from those with other varieties of respiratory disease. If all specimens had come from patients with lobar pneumonia, undoubtedly a larger percentage of Type I and Type II pneumococci would have been found. The six commonest types of pneumococci found in this large group were Types I, III, VIII, II, V and VII, in the order named. These were found in 41 per cent of all specimens examined, or 67 per cent of all specimens containing pneumococci which could be typed.

Table 2. Six Commonest Types of Pneumococci Found in the Examination of 9737 Specimens from Patients with Respiratory Disease

TYPE	NO. OF CASES
I	1485
III	1022
VIII	495
II	373
V	284
VII	233
Total	3903

The fatality rates for cases treated with specific serum in the early part of the Massachusetts study and the results reported elsewhere in this country clearly showed that the maximum benefit of serum treatment was obtained when such treatment was begun within the first four days of illness, and further that the serum then available was useful for treating only Type I and Type II cases. As a consequence, it was decided to broaden the scope of the plan and inform all physicians that under

certain conditions they could obtain serum from the laboratory of one of their near-by hospitals where there was a technician who had qualified in pneumococcus typing at the State laboratory. These conditions were

- 1 Sputum or other material from the patient shall first be typed and shown to contain Type I or Type II pneumococci
- 2 The physician must be willing to certify that his patient has not been ill with pneumonia longer than four days (ninety six hours)
- 3 The physician must agree to fill out and return to this department, when his patient is discharged, a brief questionnaire which will be furnished to him with the serum

Upon meeting these requirements, physicians would receive an average dose of serum, or 60,000 units for Type I cases and 100,000 units for Type II cases.

Table 3. Fatality Rates of Cases of Pneumococcus Pneumonia Treated with Concentrated Serum within 96 Hours of Onset, and Those Not Given Serum

	NO. OF CASES	DEATHS	FATALITY RATE %
TYPE I			
Treated with serum*	1043	145	13.9
Treated without serum†	1514	403	25.0
TYPE II			
Treated with serum*	231	63	22.4
Treated without serum†	992	407	41.0

*Massachusetts Pneumonia Study cases from January 1931 to June 30 1937

†Cases collected from the American and Canadian literature 1912 to 1933

Provision also was made to distribute an additional amount of serum to any patient whose temperature failed to fall below 101°F by mouth within eighteen hours of beginning treatment, or, if having fallen, it rose above this level within forty-eight hours. The extra amount of serum was also made available for patients having a pneumococcus Type I or Type II bacteremia, or who were pregnant or had been delivered within the previous seven days.

This plan was at first put into practice in restricted areas and when it was found feasible and acceptable to the physicians the services of the collaborators were discontinued. Since the latter part of 1935 serum has been available to all physicians throughout the State from near-by hospitals.

RESULTS OF SPECIFIC SERUM TREATMENT

In Table 3 are included only those Type I and Type II cases that received the serum treatment within 96 hours of onset and who were given not less than 16 cc. of serum or 20,000 units of antibody.

Early this year we began to distribute serum for Type V cases. The few that have been treated thus far with this product have shown a very favorable response, as shown in Table 4.

pneumonia serum, was recognition of the fact that even though a health department may be unable to prevent the spread of certain infections, it can do much to reduce the resultant loss of life. Long before it was possible to control diphtheria through immunizing procedures, health departments distributed antitoxin, and thereby achieved a decrease in deaths even if not in incidence. If the concentrated pneumonia serum as developed by Felton was capable of reducing the fatality rate for certain types of lobar pneumonia, why should not the State, through its official health agency, make the same services available for this disease, which claims almost two thousand victims each year, as had so long prevailed for diphtheria, which had formerly numbered its victims in the hundreds? Such was the basic guiding thought behind the Massachusetts pneumonia study.

Before any plans for general serum distribution could be considered, it was necessary to show that the serum could be used effectively in home practice and in the small hospitals. This was essentially a problem of field research. These early findings showed that, with proper instructions, the general practitioner could use serum as effectively as could the large metropolitan hospital centers. Such a conclusion was important inasmuch as the number of pneumonia patients who reached these large hospitals early enough to benefit much from serum was but a fraction of the total number of cases in Massachusetts.

During the latter part of the pneumonia study the coincidental development of the Neufeld method of typing pneumococci in the sputum provided rapid and simple laboratory procedures which were within the reach of any laboratory employing adequately trained personnel. Equally important was the elimination of the long delays that formerly attended most type determinations. The introduction of the Neufeld method furnished the key to the problem of controlled serum distribution in that it made it possible to restrict the distribution of serum to those who might reasonably be expected to profit from its use. Such a limitation was essential if so costly a serum was to be distributed at public expense. That the plan so evolved was administratively sound has been well shown by experience extending over the past two years.

Improvements in the methods of serum production were equally essential to the success of the Massachusetts program. These improvements were realized both as a part of and independently of the study so that the serum as distributed today is a more refined and more effective product than was that generally available in 1931.

The study would have been but a partial suc-

cess had it merely demonstrated certain administrative principles or elicited certain scientific truths. Its true success must be measured by the extent to which its findings could be applied in practice. It is therefore significant that with the completion of the five years of formal study, financed by the Commonwealth Fund, the Department of Public Health was able to take over as a part of its program the services which had been found to be essential for the continued manufacture and use of pneumonia serum. Thus the distribution of this serum has become as integral a part of the public health program of the State as is the distribution of other serums or the supervision of the milk and water supplies. The serum is now readily available in all parts of the Commonwealth, and the study has accomplished the ends for which it was designed.

Whatever success may have attended this study was due in large measure to the wise counsel and guidance of the advisory committee on pneumonia, composed of representatives of Boston University, Harvard and Tufts College Medical schools, the medical profession at large, and interested public health workers, and also to the hearty co-operation of the collaborating clinicians throughout the State. In even larger measure was its success due to the skill and ability of Dr. Roderick Heffron, who has served as field director from the beginning of the study in 1931 up to the present time. I am indebted to him for the statistical material contained in this paper.

The Final Report of the Massachusetts Pneumonia Study and Service, giving in detail the results of the five-year study, has been published,¹ and copies are available on request.

The educational work was carried on with the physicians throughout the Commonwealth through the State, county, and local medical societies. It was realized that the rapid advances in the newer methods of pneumococcus typing and serum production and concentration, with resulting changes in procedures used in the serum treatment of pneumococcus pneumonia, made this necessary, as otherwise the average physician would be unable to co-operate fully or take advantage of the serum offered to him. From the attendance at these meetings it is estimated that 75 per cent of the physicians outside the Boston area were directly reached in this way. Within metropolitan Boston a smaller percentage attended the meetings. All physicians in the State were circularized a number of times, and sent reports as the study progressed.

There has been a steady increase in the demand for pneumococcus typing since the work began. The demand for therapeutic pneumonia serum has likewise increased, and especially so since the latter part of 1935, by which time serum was avail-

ing in every instance where pneumococci other than Types I and II are found in the sputum

In addition, emphasis must be placed on the great need of taking a blood culture of every patient with pneumonia. The physician must know whether bacteremia exists, for in the presence of such a condition larger doses of serum are necessary to bring about the desired result, as serum is the only specific treatment known today which will counteract the effects of bacteremia and sterilize the blood stream.

In the first five years of the pneumonia study serum was used by about 387 physicians. Since that time, in a period of about eighteen months the number of physicians using serum has increased to approximately 1100, or about one in six of the total number in the State.

The fatality rate of serum-treated Type I cases has been a little higher since January 1 of this year. Blood-culture studies in the group suggest that possibly the pneumonia was of a more severe form than in previous winters. This may in part explain the increase in mortality. Another factor to be considered is that more physicians are using

serum and that many of them have not had the experience necessary to employ it most effectively. Possibly the higher fatality rate of 14 per cent in Type I cases during the past twelve months is a more accurate index of what the general practitioner may be expected to accomplish with serum than was the previous figure of 10 per cent, which was based on treatment of cases by a selected group of physicians who had previously been instructed in serum therapy.

We are now preparing serums for Type VII and Type VIII infections, and these will be ready for distribution in the near future. We shall then have therapeutic serum for five specific types of pneumococci available to physicians without cost to their patients. When physicians as a class become experienced in its use, it is not too optimistic to forecast a reduction of at least one half in the case-fatality rates for this group, which constitutes about 60 per cent of all lobar pneumonias.

PHYSICAL AND CLINICAL OBSERVATIONS ON THE USE OF MILLION-VOLT X-RAYS

RICHARD DRESSER, M.D.,* AND JACK SPENCER, M.D.†

BOSTON

X-RAY therapy is occupying a place of increasing importance in the treatment of malignant disease. In 1936, there were 3679 x-ray treatments given in one of the large hospitals in Massachusetts, whereas there were only 386 radium applications. During a corresponding period in 1937 the x-ray treatments in this institution increased to 4294 and the radium applications decreased to 290, that is, there was a 17 per cent increase in x-ray work and a 25 per cent decrease in radium work. A large percentage of the radium applications were made in cases of cancer of the skin. These cases could have been more effectively treated with modern x-ray apparatus.

This diminished use of radium is somewhat paradoxical. It has been the observation of most workers in radiation therapy that the shorter, more penetrating rays such as those obtained from radium give the best therapeutic results. This applies particularly to deep-seated neoplasms. In order, however, to deliver an effective amount of radiation to a tumor located near the center of the

body, the radiation must not only be composed of short wave lengths but its source must be placed at some distance from the body. Although the gamma rays of radium constitute the shortest wave lengths which have yet become available for cancer therapy, the application of radium at a distance is not practical because of its great cost and scarcity. It has therefore been the endeavor of physicists and engineers to produce, at comparatively moderate cost, x-rays which will approximate in wave lengths the gamma rays of radium and which will be available in quantities equivalent to the output of many hundreds of grams of radium element. Since the shortest wave lengths in an x-ray beam are dependent on the voltage at which the rays are produced, the problem resolves itself into the development, first, of a reliable source of high voltage and, secondly, of an x-ray tube which will operate continuously and reliably at this high voltage. The term "supervoltage" is commonly applied to x-rays which are produced at potentials greater than 200,000 volts.

This problem of supervoltage x-ray generation has been approached by a research group at the

†Assistant roentgenologist, Collis P. Huntington Memorial Hospital.

The importance of the administration of pneumonia serum early in the course of the disease is shown in Table 5. Our policy until recently

Table 4 *Fatality Rates of Cases of Type V Pneumococcus Pneumonia Receiving Treatment with Concentrated Serum within 96 Hours of Onset and Those Not Given Serum*

†Cases collected from American literature.

has been to distribute serum only for use in patients who had been ill not more than four days. The experience of various investigators, however, has demonstrated quite consistently that although serum treatment is begun later than four days, it may in some instances save lives. In accordance

Table 5 *Type I Cases Treated with Serum: Number and Percentage of Deaths by Day on Which Serum Treatment Was Begun*

SERUM TREATMENT BEGUN	NO OF CASES	DEATHS No	%
1st day	183	26	14.2
2nd day	384	42	10.9
3rd day	294	40	13.6
4th day	182	37	20.3
Totals	1,043	145	
Average			13.9

with this evidence we have modified our plan, and while still stressing the importance of early treatment have made serum available for any case of pneumonia of the right type, regardless of the length of time the patient has been ill.

Of the grand total of 1341 Types I, II and V cases, 326 or 24.3 per cent were treated at home.

SERUM DOSAGE

We recommend the administration of at least 60,000 units for all Type I cases and 100,000 units for those of Type II, and additional doses of from 40,000 to 60,000 units at three- or four-hour intervals for all patients who have bacteriemia, are pregnant or have been delivered within seven days, are forty years of age or over, have involvement of more than one lobe, or whose treatment is begun on the fourth day of the disease or later. Similar extra doses are advised when the temperature does not fall below 101°F by mouth (102°F by rectum) within eighteen hours of beginning serum treatment, or when the temperature rises above that level within seventy-two hours after the initial drop.

BACTERIEMIA

Of a grand total of 1341 Type I, II and V cases treated with serum, 635, or 47.4 per cent, had blood

cultures done. About 26 per cent of Type I, 29 per cent of Type II and 24 per cent of Type V cases showed positive blood-culture results. As noted in Table 6, the fatality rate for the cases with positive blood cultures was high. The findings in our series suggest that the incidence of positive blood cultures increases with age, a phenomenon which may partially account for the high fatality rate in the older age group.

Table 6 *Type I and Type II Cases with and without Bacteriemia Treated with Serum: Number and Percentage of Deaths*

BLOOD CULTURES	TYPE I			TYPE II		
	NO OF CASES	DEATHS	FATALITY RATE %	NO OF CASES	DEATHS	FATALITY RATE %
Negative	340	28	8.2	113	17	15.0
Positive	112	32	28.6	47	22	46.8

Table 7 shows that when bacteriemia is present there is more marked proportional increase in the fatality rate in patients 0-49 years old (400 per cent) than in the older patients (200 per cent).

Table 7 *Fatality Rates of Cases of Pneumococcus Pneumonia in Different Age Groups Listed According to the Presence or Absence of Bacteriemia*

Positive	34	13	38.2	13	9	69.2

PNEUMOCOCCUS TYPING

The demand for pneumococcus typing at the State Bacteriological Laboratory continues to increase, and is more than 25 per cent higher than it was two years ago when the study period ended. Over seventy hospital laboratories now have qualified technicians and are doing their own typing. These laboratories are supplied with diagnostic serums by the department. We estimate that specimens of sputum are sent to some laboratory for typing in about one fourth of all the pneumonia cases in the State.

A review of the typing figures and a careful survey of treated cases clearly indicate the need of a more intensive effort on the part of the physician to have determined the type of pneumococcus infecting the patient whom he is treating. When the first sample of sputum fails to reveal pneumococci, or the findings are questionable, other specimens should be submitted for examination. Further, second specimens should be sent for typ-

treatments during the first six months' period seems desirable. They are grouped as follows:

Cancer of the breast	21
Malignancy of the buccal cavity	15
Cancer of the bladder	17
Cancer of the cervix	11
Cancer of the prostate	4
Ovarian carcinoma	5
Cancer of the larynx	3
Renal tumors	2
Cancer of the esophagus	3
Hodgkin's disease	3
Carcinoma of the large bowel	3
Embryoma of the testicle	3
Miscellaneous	18

The irradiated breast cases have been either in the inoperable group or in that group showing recurrence after operation. Regression of local disease has been as prompt as one would expect after 200,000-volt therapy, but there have been less skin reaction and less roentgen sickness. In a case which was given an unusually large dose, a reaction which might be attributed to damage from radiation was noted in the lung. This patient, however, developed bone metastases, and it is not improbable that these changes were due to metastatic disease rather than to radiation pneumonitis.

There are certain advantages in treating carcinoma of the mouth and throat at very high voltage. Coutard³ has shown that in order to control malignancies in this region with 200,000-volt therapy, doses must be administered which actually destroy the outer layer of the skin and occasionally result in rather painful, slowly healing ulcerations. At higher voltage the same effective dose may be delivered to the tumor, but with no further skin effect than a mild, scarcely noticeable erythema. If indicated, the radiation may be repeated after an interval of several months, which is not possible following an adequate dose of 200,000-volt x-ray.

The group of bladder tumors has proved most interesting. In a recent review by Graves and Dresser⁴ of a series of cases of carcinoma of the bladder treated at 200,000 volts, it was found that little more than a moderate degree of palliation was afforded. The immediate results, however, from 1,000,000-volt therapy have been much more encouraging. All these cases have been hopeless from a surgical point of view or have shown recurrence after operation. In almost every instance there has been either partial or total regression of the tumor with symptomatic relief. With one ex-

ception there was no untoward general or local reaction.

Most of the cases of carcinoma of the cervix uteri have been previously irradiated either with low-voltage x-ray or radium. They have, therefore, constituted a very unfavorable group. A recent review by Meigs and Dresser⁵ of three-year results obtained at the Pondville Hospital by combined 200,000-volt x-ray and radium treatment has proved beyond doubt the value of this method. It is anticipated that a combination of x-ray and radium, using 1,000,000-volt rays instead of 200,000-volt, may lead to even more gratifying results.

Much palliation has been afforded in all the cases with carcinoma of the prostate, but in no instance has there been complete disappearance of the neoplasm.

One case of carcinoma of the esophagus is now entirely symptom free, presents a normal esophagus by x-ray examination, and is gaining weight. A second case has had no relief from obstruction and the patient has just been submitted to a gastrostomy. He has recovered satisfactorily from the operation, and further intensive radiation to the esophageal growth is planned.

It is the intent to irradiate reasonably large groups of cases with malignancies of various types so that statistical data as to the success or failure of this treatment will ultimately be available. Our observations thus far lead us to believe that in the treatment of deep-seated neoplasms the immediate results of 1,000,000-volt x-ray therapy, even though they may prove to be only palliative, are superior to those obtained with lower voltages. The regression or complete disappearance of new growths takes place with little or no untoward general reaction on the part of the patient, and apparently with less damage to normal tissues than has heretofore been observed.

Massachusetts Institute of Technology from an entirely new angle. Through the generosity of the Godfrey M. Hyams Trust it has been possible to construct a new type of x-ray generator at the Collis P. Huntington Memorial Hospital. This unit has been described in a recent paper by Trump and Van de Graaff,¹ and another article dealing with the mechanical construction and physical characteristics of the rays produced has been written by Dresser, Trump and Van de Graaff.² During the first six months of operation 101 patients suffering with malignant disease have been treated, and certain physical investigations have been carried out. There are a number of mechanical advantages in this type of apparatus, and there have been obtained certain gratifying immediate therapeutic results which seem worthy of note.

The machine has been operated routinely at a constant potential of 1,200,000 volts, which we believe is the highest effective voltage ever used for therapeutic x-ray production. The average wave length of the beam approaches that of the rays of radium. The quantity of radiation has been estimated as equivalent to that which would be obtained from 2000 grams of radium element—an amount greater than all the refined radium in the world. The apparatus is mechanically as reliable as any of the low-voltage commercial x-ray units, in fact, during the first six months of operation it has been necessary to postpone treatments for only one day.

Although statistical results of the treatment of various types of malignancies will not be available for several years, we feel that certain pronounced differences which we have already noted between the results of this type of radiation and of the usual 200,000-volt treatment should be reported. The skin will tolerate twice as much x-ray delivered at 1,000,000 volts as it will at 200,000. Moreover, if equal doses of 200,000-volt and 1,000,000-volt x-rays are applied to the skin, about 20 per cent more of the latter will reach the center of the body. The combination of these two factors, that is, the greater skin tolerance and the greater penetrating power, allows the administration of more nearly adequate amounts of radiation to deep-seated tumors without appreciable damage to the superficial tissues. Following treatment with 200,000 volt x-rays many patients suffer from moderate to severe roentgen sickness. This is characterized by general malaise, loss of appetite, nausea and sometimes severe vomiting. There is surprisingly little roentgen sickness following million-volt therapy. This is well illustrated by the following case:

A patient with extensive cancer of the breast was irradiated at 1,000,000 volts through a large portal including the lateral aspect of the breast and the axilla. The medial portion of the breast was subsequently treated at 200,000 volts through a smaller portal. The dose administered was exactly the same with both types of radiation. The patient suffered no untoward symptoms of any kind following the 1,000,000-volt treatments, but experienced nausea and vomiting after each of the 200,000-volt exposures.

The diminution in roentgen sickness now makes it possible to irradiate many patients as ambulatory cases who otherwise would have to be hospitalized for several weeks.

Unfortunately, there is no yardstick with which to measure our results. Evaluations must be made after frequent and careful observations of the patients irradiated, and mental comparisons made with results obtained during a long experience with low-voltage x-ray therapy. It is our impression that satisfactory results are to be expected only in those tumors which have shown themselves to be in some degree sensitive to low-voltage radiation. The sensitivity of a tumor cannot always be predicted from its histology, and we are therefore obliged to irradiate many seemingly unfavorable cases in the hope that some of them will constitute the exceptions to the rule.

It is exceedingly important to treat with caution those patients who are in poor general condition or who have very extensive malignancies. Much unnecessary suffering may be caused if this rule is not followed. The radiologist soon learns, however, that careful handling of seemingly hopeless cases may occasionally produce surprising results. The first case treated on the 1,000,000-volt unit illustrates this point.

Having checked the machine as carefully as possible with ionization measuring instruments, a small group of patients was selected for trial dosage. The first patient chosen was one suffering from carcinoma of the larynx. He had been previously treated by radium implantation and by heavy doses of 200,000-volt x-rays. Even though we were dealing with a presumably radiosensitive tumor, the disease was progressing in spite of this therapy, and it was anticipated that the duration of life would not be more than a few weeks. Following repeated small doses of 1,000,000-volt x-rays, designed primarily to determine the skin effect, the patient to our surprise showed improvement. Radiation was then continued in somewhat larger amounts, and today the patient is clinically free of disease.

The anthesis of this case is one of a melanotic sarcoma recurrent after operative removal. It is well known that this type of lesion is exceedingly radioresistant. Although the tumor was heavily treated with 1,000,000-volt x-rays there was, as anticipated, no response.

A brief analysis of the 101 cases that received 824

tion is quite conclusive. Many cases with active pulmonary disease are observed which have positive stools with no intestinal lesion, and many others with tuberculous mesenteric lymph nodes or tuberculous peritonitis and no lesions in the intestine. This simply substantiates the general belief that in many cases the intestine is immune to tubercle bacilli in the stools. The fact that 34 per cent of the cases of intestinal tuberculosis occurring in the British Isles, where much of the milk is tuberculous, are primary lesions favors the ingestion theory.

There is considerable evidence that the tubercle bacilli are carried by the blood stream in many cases of enteritis, from a ruptured cavity in the lungs or from lymph nodes, as stated by Archibald,¹⁰ Calmette¹¹ and others. Cases with negative sputum and stools at least are very suggestive of transmission by the blood stream.

The initial lesion in the intestine in from 80 to 90 per cent of patients is in the terminal ileum and cecum (Brown and Sampson,⁴ Granet,³ Archibald¹⁰). The susceptibility of this region to the tubercle bacilli is thought to be due to the increased blood supply, the greater number of Peyer's patches and solitary follicles, and stasis of the fecal stream.

The ulcerative type of lesion in most cases extends upward in the ileum from the original focus, forming circular or girdle ulcers of the mucosa or, less frequently, longitudinal or multiple small ulcers. The edges of the ulcers are ragged and the floor is covered with tubercles. The wall of the intestine over the ulcer is often thickened, and the peritoneum is congested and covered with exudate and tubercles. Adherence of loops of intestine at the site of ulcers is common, penetration of ulcers through the muscular layers occurs, although not commonly. Perforation is a rare complication on account of adhesions at the ulcer site. Abscesses and fistulas are not uncommon. As the ulcers heal, obstruction of varying grades may occur, due to angulations and narrowing of the lumen resulting from adhesions or fibrosis of a girdle ulcer with stricture.

The hyperplastic type of disease develops in practically all cases in the ileocecal region, but in a small percentage it extends to other sites in the large intestine or in the rectum and anus. It is rarely if ever found in the hepatic or splenic flexures. Hyperplastic and ulcerative types of lesions may occur simultaneously in the same patient. Hyperplastic lesions are characterized by formation of a tumor, often of considerable size, resulting from the production of granulation tissue in the submucous and to a lesser degree in the subserous coats of the intestine. Ulceration of the mucosa may occur, more frequently the increased

thickness of the intestinal wall causes a narrowing of the lumen, resulting in obstruction. The adjacent lymph nodes are enlarged, increasing the size of the tumor and giving the gross appearance of carcinoma.

Intestinal tuberculosis in most cases has an insidious onset. Patients with pulmonary disease have a loss of appetite, mild indigestion, constipation or diarrhea, loss of weight, an unexplained slight fever, and abdominal pain which may be generalized but is more frequent in the right lower quadrant. The pulmonary lesion remains at a standstill or shows evidence of activation. Gastrointestinal x-ray studies at this stage are frequently inconclusive.

As the disease progresses, nausea and vomiting occur, abdominal pain more definitely located in the right lower quadrant and aggravated by eating, diarrhea, — often of a severe type, — distention and more marked loss of weight are observed.

In the hyperplastic type, — abdominal pain is more definitely located in the right lower quadrant in the early course of the disease. Later a tumor is palpable in this region, often with symptoms of obstruction. Many of these patients are subjected to abdominal exploration, when the correct diagnosis is established and an unoffending appendix is removed.

X-ray diagnosis in these cases is based upon the so-called Sierlin phenomenon, or a filling defect and hyperirritability of the cecum. A persistent irregularity and spasm of the ileocecal valve is also observed. In many cases there is a marked narrowing of the terminal ileum. The ulcerative type of disease is characterized by a segmentation and dilatation of distal loops, giving the appearance of a string of sausages.

The diseases most commonly considered in a differential diagnosis are cancer, regional ileitis, ulcerative colitis and nonspecific granuloma. In cancer the patients are usually older, blood in the stools is commoner, and emaciation and anemia are more pronounced than in intestinal tuberculosis. The symptoms of regional ileitis in its early course are suggestive of an acute inflammatory lesion or may simulate ulcerative colitis, obstruction, perforation, abscess and fistulas are later manifestations. Intractable diarrhea, characteristic stools and prostration help to distinguish ulcerative colitis. Nonspecific granuloma is frequently mistaken for hyperplastic tuberculosis, clinically and in x-ray studies. The gross specimen and microscopic section closely resemble those of tuberculosis. Wilensky and Moschowitz¹² state that many cases of nonspecific granuloma have been incorrectly diagnosed as tuberculosis by pathologists.

In the past fifteen years the results of the use of heliotherapy and ultraviolet rays in the treat-

INTESTINAL TUBERCULOSIS

GEORGE ALBERT MOORE, M D *

BROCKTON, MASSACHUSETTS

INTESTINAL tuberculosis occurs in the great majority of cases as a complication of advanced pulmonary disease. Treatment of the intestinal lesion in these cases is obviously of little avail as regards ultimate prognosis, although with modern methods improvement of the enteric disease is a not uncommon observation.

In the cases of intestinal tuberculosis without active disease elsewhere, the results of treatment are more favorable, but the mortality still remains high. One writer¹ has stated that our treatment of intestinal tuberculosis today is comparable to the treatment of pulmonary tuberculosis of ten years ago.

Routine gastrointestinal x-ray examinations in tuberculosis sanatoriums show that the number of cases with intestinal ulceration varies from 17 per cent (Veterans' Hospital, Sunmount, New York,²) to 38 per cent (Metropolitan Hospital, New York City³). Brown and Sampson⁴ at Saranac Lake made a clinical and x-ray diagnosis of ulcerative enteritis in 26.4 per cent of 5542 patients with pulmonary disease. They have checked a series of these cases at operation and autopsy and have found their diagnosis correct in over 90 per cent.

A still higher incidence of intestinal ulceration is found at autopsy in cases of fatal pulmonary tuberculosis. Brown and Sampson⁴ 60 to 90 per cent, Granet⁵ 72 per cent, Kaufman⁶ 90 per cent. Intestinal tuberculosis not only ranks the highest as a complication of pulmonary disease, but also increases the problem of treatment on account of the difficulty in maintaining nutrition. In many pulmonary cases the inception of intestinal symptoms is coincident with a downward course with fatal termination.

In our tuberculosis sanatoriums in Massachusetts, funds for routine gastrointestinal studies of pulmonary cases are not available. Statistics† from ten of these hospitals showing the incidence of tuberculous enteritis in pulmonary cases as compared with institutions where routine gastrointestinal studies are made are of interest. Of 6401 cases with pulmonary tuberculosis treated, a clinical diagnosis of intestinal tuberculosis was made in 391 or 6.1 per cent. In two sanatoriums‡ in Maine 538 pulmonary cases were treated in 1935-1936, 76 or 14 per

cent were diagnosed as intestinal tuberculosis. Statistics⁷ for Connecticut show 2007 cases of pulmonary tuberculosis treated from 1934 to 1936, in none of which was a diagnosis of intestinal tuberculosis made. At the Massachusetts General Hospital⁷ since 1900 there have been 195 cases diagnosed as intestinal tuberculosis, 9 with tuberculous appendicitis, 52 with rectal tuberculosis and 24 with tuberculosis of the anus.

At the Lakeville Sanatorium, which is devoted exclusively to extrapulmonary tuberculosis, we have treated 39 patients with intestinal tuberculosis. This small number is explained by the fact that we admit no patient with active pulmonary disease. During the same interval we have treated 82 patients with tuberculous mesenteric glands and 133 cases of tuberculous peritonitis.

State and federal statistics regarding the incidence of intestinal tuberculosis are not available, since tuberculous peritonitis, mesenteric lymph nodes and intestinal tuberculosis are grouped together. In these three groups there were 2501 deaths from 1912 to 1935 inclusive in Massachusetts.⁸ The highest number, 202, occurred in 1916, the lowest, 31, in 1934. In the United States⁹ there was a yearly average of 2200 deaths from these three diseases from 1930 to 1932, inclusive, which dropped to 1431 in 1935.

These statistics are subject to many errors, and obviously are not based upon intestinal tuberculosis seen as a complication of pulmonary disease. They are, however, decidedly hopeful.

The hyperplastic type of intestinal tuberculosis, characterized by a marked thickening or hyperplasia of the intestinal wall, occurs much less frequently than the ulcerative, since it is seldom found as a complication of pulmonary disease. Lockhart Mummery⁹ reported 100 cases of this type, in 76 of which no other tuberculous lesion was found. By many writers it is described as a primary tuberculous lesion. This statement has been questioned, since 50 per cent of children have bovine tuberculous foci and about 90 per cent of adults have tuberculous infections during their lives. An intestinal lesion may have its origin in an arrested focus in the lungs, the lymph nodes or elsewhere in the body.

The route of transmission of tubercle bacilli to the initial lesion in the intestine is still unsettled. In the presence of positive sputum or of bacilli in the stools or breast milk, the evidence for inges-

‡Plymouth County, Westfield, Belmont, Rutland, Essex, Bristol, North Reading, Norfolk, Worcester and Springfield Health Department hospitals and sanatoriums.

§Western Maine and Central Maine sanatoriums.

signs of pulmonary disease were found. An enterostomy was done without benefit, and death ensued the following day. At postmortem, hyperplastic ileocecal disease and complete transposition of viscera were found.

Case 3 Mr McQ., aged 46, was admitted to the Moore Hospital on March 5, 1925. He had had general abdominal pain, indigestion without relief by food, and frequent attacks of severe pain in the right lower quadrant for 5 years. Hyperplastic ileocecal disease and numerous annular strictures of the lower ileum were found at operation. An ileostomy resulted in temporary relief. He was sent to a sanatorium, where he died in 1927.

Case 4 F C., a 28-year-old woman, was admitted to the Lakeville Sanatorium on January 14, 1937. In August 1933, an appendectomy had been done in the Salem Hospital, and was followed by a fecal fistula. In December, 1933, the fistulous opening was closed, but it promptly reopened. She was sent to the Massachusetts General Hospital, and in July, 1936, a transverse colostomy and repair of the fecal fistula in the rectosigmoid was done. The fecal fistula again reopened and a urinary fistula developed both of which still persist. Guinea pig inoculation at Lakeville gave a positive reaction. She now has a large firm tumor in the right lower quadrant, extending into the pelvis and apparently involving the bladder. Her general physical condition is steadily improving under the usual treatment with ultraviolet light despite the extensive local disease.

Case 5 L. R., a 21 year-old colored man, was admitted to the Lakeville Sanatorium in April, 1936, for tuberculosis of the 9th, 10th, and 11th dorsal vertebrae. Gastrointestinal x rays were taken at another hospital before admission, with a report of almost complete obstruction of the ileum from an old appendix abscess or tuberculous peritonitis. In June, 1936, a fusion operation of the spine was done by Dr. Z. B. Adams. Abdominal symptoms persisted, characterized by pain in the right lower quadrant and a gradually increasing tumor in this region, and in October, 1936, he was referred to me for marked signs of obstruction. He was relieved of his obstruction by conservative treatment, and at operation a resection of the terminal ileum and cecum and a lateral anastomosis were done. A very stormy convalescence followed, complicated by a fecal fistula which required closure. The patient is now free from abdominal signs of disease but has bilateral renal disease.

SUMMARY

1 Ulcerative enteritis is found postmortem in from 65 to 90 per cent of patients with fatal pulmonary tuberculosis. The hyperplastic type of intestinal tuberculosis occurs much less frequently, and in many patients no active disease is manifested elsewhere in the body.

2 There is considerable evidence that tubercle bacilli are transmitted by the blood stream. It appears that in the great majority of cases of intestinal tuberculosis the organisms are ingested and transmitted by the digestive tract.

3 The initial lesion in over eighty-five per cent of cases is in the Peyer's patches and solitary follicles in the terminal ileum and cecum. The process may spread upward in the ileum, characterized by ulceration. It may remain at the site of origin or extend distally in the form of hyperplastic disease or in combination with ulcerations.

4 The early symptoms are insidious and are characterized by digestive disturbances and pain in the right lower quadrant. The later stages are marked by severe gastroenteritis, and in many cases, the symptoms are suggestive of an "acute abdomen." Abdominal emergencies are the result of acute obstruction, tuberculous appendicitis, perforation and abscess.

5 The most effective treatment for the ulcerative type of lesions consists in suitable therapy of pulmonary disease so as to obtain a negative sputum and stop the flow of tubercle bacilli in the intestinal tract, ultraviolet-light treatment, and proper hygiene and diet. Hyperplastic disease is best treated in most cases by some type of exclusion operation, followed by ultraviolet radiation and later excision, if necessary. Primary resection should be reserved for the rare patient who is an excellent risk. Obstruction, appendicitis and perforation do not differ in their immediate surgical indications from similar conditions resulting from diseases other than tuberculosis.

DISCUSSION

DR. JAMES W. JAMESON, Concord, New Hampshire. Dr. Moore's paper brings up a condition that is likely to be overlooked by the general surgeon unless he is connected with a tuberculosis sanatorium, because he is apt to associate intestinal tuberculosis with the advanced cases where there is extensive ulceration, intestinal obstruction, abscesses and fistulas or the hyperplastic form of tuberculosis. The diagnosis in these cases is relatively easy.

It is in the early stage of the disease that diagnosis is difficult, but when we realize that over 95 per cent of the cases with intestinal lesions have a positive sputum, we must not fail to consider an intestinal involvement in any tuberculous patient with abdominal symptoms. As only

ment of intestinal tuberculosis have been comparable to those of surgery in pulmonary tuberculosis. The greatest field of usefulness for light therapy is in the ulcerative cases, which prior to its introduction were considered almost hopeless. Brown and Sampson,⁴ have advocated its use even in the presence of advanced pulmonary disease. They have observed healing of intestinal lesions in the presence of progressive and even fatal pulmonary disease. In their series of 271 patients treated with ultraviolet rays they reported good results in 73 per cent. Our small series of cases at Lakeville Sanatorium are in most instances of the hyperplastic type of disease, and do not occur as a complication of active pulmonary disease. Our results with ultraviolet rays in these cases have been highly gratifying, although we do not use the intensive treatment advocated by Brown and Sampson.

Granet³ has shown that many cases of intestinal tuberculosis have a positive sputum and that few have a negative sputum. He advocates collapse therapy in the former if possible, in order to produce a negative sputum before the use of light therapy for the intestinal lesion.

Pneumoperitoneum has been of great benefit in the treatment of tuberculous peritonitis, and has been advocated for intestinal tuberculosis. Salkin,¹ of the Michigan State Sanatorium, has reported benefit in a high percentage of ulcerative cases. We believe, however, that this form of treatment is still in the experimental stage.

The field of surgery in intestinal tuberculosis is limited at present to the relief of intestinal obstruction, removal of the rare tuberculous appendix, an exclusion operation, or in selected cases resection of hyperplastic disease, and treatment of perforations, abscesses and fistulas.

Intestinal obstruction is a not infrequent occurrence in both the ulcerative and hyperplastic forms of intestinal tuberculosis. The treatment does not differ from that of obstruction from other causes, except that resection of the diseased intestine, if necessary, should be done at a later time.

Santy¹³ has reported a series of 20 cases of hyperplastic disease without obstruction in which a primary resection was done in 10 and an exclusion operation in the others. Light therapy was used in the cases treated by exclusion with much better results than in those treated by resection. Excision of the diseased segment was done at a later date if the disease was not completely arrested by light therapy. An operation which provides exclusion and anastomosis, with colostomy in certain cases, puts the diseased segment of the bowel at rest. With the addition of light therapy this appears at present to be the best method of healing the tuber-

culous process. In a certain number of patients healing of the disease with a functionless segment of bowel results. If an excision is necessary on account of incomplete healing, the operation is much less formidable than if done at first. The diseased bowel is usually found to be a fibrous cord of scar tissue. Nearly twenty years ago Archibald advised a bilateral colostomy in patients with tuberculous enteritis whose condition contraindicated resection.

A few cases of tuberculosis limited to the appendix have been reported. If the appendix is removed before contiguous organs are involved, a cure may be expected. Unfortunately, in most of these cases the tuberculous process is found at operation to have involved the terminal ileum and cecum. Cases of advanced inoperable ileocecal tuberculosis with severe pain may be greatly relieved by removal of a tuberculous appendix.

Perforation is a rare complication of intestinal tuberculosis, with a high mortality. Brown and Sampson,⁴ also Bérard and Patel,¹⁴ stated that it is found at autopsy in 3 per cent of patients who succumb to pulmonary disease. It occurs most frequently in the terminal stages. A clinical diagnosis is rarely made, and in most cases the patient's condition precludes operation. Ameuille and Duperrat¹⁵ reported 12 cases observed in four years, and cited from the literature 4 cases of recovery following operation. All these recoveries occurred in patients with minimal or no pulmonary lesions. Marconi¹⁶ published 21 cases of perforation collected in the literature, 5 of which recovered following operation and 16 of which died. He cited 1 case of his own which recovered following operation.

The more characteristic manifestations of intestinal tuberculosis are illustrated by a brief review of some of the cases in my private practice and at the Lakeville Sanatorium.

CASE REPORTS

Case 1 Mrs. A., aged 40, was admitted to the Moore Hospital on December 11, 1917. She had had active pulmonary tuberculosis and had been treated in a sanatorium. She was 6 months pregnant at the time of onset of acute symptoms. Increasing constipation for six weeks was followed by obstruction for 5 days before admission. At operation, loops of terminal ileum were adherent and an enterostomy was done proximal to the obstruction. Miscarriage ensued 12 hours later. Two and a half months later the diseased ileum was resected and an anastomosis was done. The patient's condition in May, 1937, was excellent.

Case 2 Mr. S., aged 30, who was admitted to the Moore Hospital on July 20, 1922, gave a history of general abdominal pain, indigestion, attacks of severe constipation and of vomiting, and loss of weight for the past 5 years. He had had no bowel movement for 3 days prior to intervention, and there were the usual signs of obstruction. No

Dana in 1886, and the first successful American case was reported by Abbe in the *Boston Medical and Surgical Journal* in 1896. This operation, known as rhizotomy, has long since fallen into disrepute because of the great overlapping of the sensory nerve supply. It was found necessary to cut at least three roots above a lesion, and if the disease was widespread the ordeal proved too great for most of these already debilitated patients.

Moreover, by 1911 Spiller and Martin had published their first case of chordotomy. This operation depends for its success on the fact that pain and temperature fibers after entering the cord cross over and pass up the cord in the anterolateral region. Our knowledge of this pathway begins with a suggestion by Gowers in 1879, which was more emphatically stated by Van Gehuchten in 1893, but it was Spiller's brilliant clinical proof in a patient that led in 1904 to his endorsing the procedure. The operation is quite simple and may be performed under local anesthesia, since dividing the pathway in the cord is not painful. The dura is opened, the arachnoid is incised, a dentate ligament is separated from the dura near the desired root, its dural end is seized in a clamp, and by pulling on this the cord is rotated until the ventral root is clearly seen. A cataract knife or the special hook and knife devised by Frazier are then used to divide the anterolateral bundle. The incision should start at the dentate ligament, enter to a depth of 2.5 to 3 mm., and emerge at the ventral root. A considerable number of such procedures have been done, Grant alone reporting 51 in 1930. The operation has its opponents and proponents. Stookey has shown relief with only a 1.5-mm incision, which he thought preserved the more deeply situated temperature fibers, but Foerster holds that in a unilateral procedure the incision must be very deep and must enter the gray matter if pain is to be obviated. Davis believes that the deeper incision into the gray matter is more apt to obviate pain, since it also divides certain sympathetic fibers there, which he thinks are the source of the pain in unsuccessful cases. The operation should be carried out from four to five segments above the uppermost involved lesion. It is more successful if bilateral, in which case different levels should be used on the two sides. It may be done in the lower cervical region, but is usually performed for lower spine or pelvic lesions, in which the upper thoracic level is simplest and safest. There are obvious dangers: hemorrhage may cause serious motor weakness, from 10 to 20 per cent of patients have bladder difficulty, which may be very bothersome, and in debilitated patients with a prospect of short life, the

risk may not be worth while. For traumatic lesions of the spine, however, and other benign conditions it is eminently desirable. More recently (1934) Dr. Tracy Putnam suggested division of the spinal commissure when the painful disorder was confined to the thorax and arm. Chordotomy for this area, placing the operation high in the cervical spine, is too dangerous, and rhizotomy of the upper cervical nerve renders the arms practically useless. Dr. Putnam has invented a small myelotome which can be inserted in the dorsal fissure and thus used to divide the fibers at the decussation. One can only say that the objections to the procedure would be its magnitude in patients obviously very ill.

Lastly, to combat this painful spinal condition, again usually due to metastatic carcinoma, we have relief by the subarachnoid injection of alcohol. This was introduced by Dogliotti in 1931, and is so simple and safe that in my opinion it will largely supplant the surgical procedures already outlined for extensive malignant disease in the pelvis. The considerations are simply that alcohol is lighter than cerebrospinal fluid and will therefore float upon it. The patient is placed on his normal side, and so angulated that the uppermost part of the cord contains the spinal roots by which painful stimuli enter the cord. By slightly tipping the patient ventrally, the motor root is further protected. From 1 to 2 cc of alcohol is then slowly injected, after withdrawing a corresponding amount of cerebrospinal fluid. Dogliotti used absolute ethyl alcohol, but following the suggestion of Dr. Tracy Putnam we have used a mixture of 60 per cent absolute ethyl alcohol and 40 per cent absolute methyl alcohol in most of our cases. The manner of action of the alcohol is unknown. Dogliotti believed that it destroyed certain fibers in the dorsal root. Perhaps like other anesthetic agents, it affects sensory nerves more than it does motor nerves. Our cases have been chiefly those with carcinoma of the cervix, bladder or prostate, causing pain from local pressure in the pelvis. Until more is known about how the alcohol acts, such a procedure should be confined to the relief of intractable pain in patients with advanced cancer. In our hands, 50 per cent of the cases have had highly successful results. Where incomplete relief was obtained the areas of anesthesia did not coincide with the areas of pain. This serves to emphasize the great importance of the position of the patient and the selection of the site for injection. For obvious reasons, alcohol is not so effective for the treatment of spinal metastases, and will possibly be reserved for intractable pain where the pain fibers enter over a small field. Thus chordotomy will still hold its place as a merciful pro-

a small proportion of tuberculous patients are treated in sanatoriums, one must keep intestinal tuberculosis constantly in mind, although the surgeon is less apt to see these cases than the internist.

My experience with intestinal tuberculosis has been limited to cases with tuberculous fistulas and to 1 case of the hyperplastic type, the results in both conditions being very unsatisfactory. The case of hyperplastic tuberculosis was that of a girl of nineteen with an active pulmonary lesion. I did a resection of the terminal ileum, cecum and ascending colon with end-to-end anastomosis of the ileum to the transverse colon. She lived about six months, and died from pulmonary hemorrhage without evidence or extension of the intestinal lesion.

DR. MOORE (closing) I am going to show a few x rays to illustrate the filling defects of the terminal ileum but more especially those of the cecum, the so-called Sterlin defect, which is considered characteristic of tuberculosis.

In regard to treatment, I should like to emphasize again that heliotherapy and ultraviolet radiation in the ulcerative type of disease have proved to be of great benefit. In hyperplastic intestinal tuberculosis, heliotherapy and ultraviolet radiation have not been used so extensively because this form of the disease is less frequently observed, and also because it is not commonly seen in sanatoriums. In conjunction with some type of exclusion operation the results have been decidedly encouraging as compared with excision of the diseased segment of intestine alone.

THE SURGICAL TREATMENT OF PAIN

ELLIOTT C CUTLER, M.D.*

BOSTON

THE presentations which have preceded my attempt to discuss the surgical treatment of pain have made it clear that there are two types of pain arising through separate mechanisms. There is somatic pain, arising in relation to changes in the central nervous system, and there is visceral and vascular pain, apparently having to do with changes in the autonomic nervous system. Somatic pain follows topographic anatomy, repeats itself in the same area, does not radiate with recurrent attacks into new fields, returns each time with more or less the same intensity and is usually discontinuous in action. Patients suffering from trigeminal neuralgia (*tic douloureux*) are an example of somatic, central-nervous-system pain. Autonomic or sympathetic pain is fickle and capricious, it occurs in a less limited field, which it frequently overflows, it varies greatly in intensity with different attacks, is aggravated by the emotions and by barometric pressure, and it bears a more distinct relation to the individuality of the patient. Patients suffering with traumatic causalgia represent this type of pain.

Pain is the symptom that brings most patients to the doctor. Fortunately its cause can usually be determined and proper therapy for its relief instituted. Such an indirect attack on pain as the removal of biliary or urinary calculi which gave rise to it need not interest us here. We have only time to discuss a few examples of the surgical treatment of pain where the treatment is directed at the nervous system itself. The surgeon must always bear in mind this rule before any operation is

undertaken that has for its primary object the denervation of a painful part, he must prove to himself that a direct attack on the lesion is impossible. Such conditions are met with when the painful area is more extensive than the local lesion, as in widespread local extension of cervical cancer, or with bony metastases, and when there is referred or visceral pain and the real lesion is either difficult of access or incompletely understood, as in angina pectoris and dysmenorrhea.

SOMATIC PAIN

A direct attack on the central nervous system may be aimed at the peripheral nerve, the posterior nerve roots or the anterolateral tracts of the spinal cord, where the pain fibers are gathered together, transection of the spinal cord has even been performed (Cushing and Leriche). These procedures have been carried out largely as merciful procedures in patients suffering from hopeless cancer or from injury to the spinal cord.

In dealing with pain in carcinoma of the face and mouth, the contributions of Grant, Mixer, Adson and Fay describe the considerable relief that can be given by alcoholic injections of the second and third divisions of the fifth nerve, by intracranial division of the fifth and ninth nerves, or by intradural division of the posterior nerve roots of the upper three cervical nerves. Such procedures may be of great help to patients, particularly when slow-growing, non-metastasizing tumors are the source of the pain.

The more usual application of this form of surgery is seen with malignant disease in the pelvis, which is inoperable, radioresistant or metastatic to the spine. Section of the posterior nerve roots was first proposed for this dilemma by

Presented at a combined meeting of the Suffolk District Medical Society and the Boston Orthopedic Club at the Boston Medical Library November 17, 1937.

Moseley Professor of Surgery Harvard Medical School Boston Massachusetts surgeon-in-chief Peter Bent Brigham Hospital Boston Massachusetts

treatment of angina pectoris was not popularized. In 1923 Coffey and Brown, of San Francisco, related their experience with 5 cases as showing that removal merely of the superior cervical sympathetic ganglion, or even division of the main branch from this ganglion to the heart, sufficed to ameliorate pain in angina pectoris. These successful results with such a simple procedure led to a general practice of operation on patients suffering with angina pectoris.

In addition to these surgical procedures there arose the method of blocking the white rami at the point of emergence from the bony spine with procaine or alcohol. This method, introduced by Mandl and Swetlow, has been ably defended and popularized in Boston by Dr. James C. White. Its simplicity, in spite of the danger of the use of alcohol so close to the pleura and spinal cord, commends its trial, and the published figures reveal results which seem comparable to the more serious and cumbersome surgical methods. Even if these procedures fail ultimately to prove of great practical value in clinical medicine, the stimulation of the study of cardiac pain and the innervation of the heart will have been a distinct benefit to the profession.

Can we interpret intelligently the results obtained by such widely differing procedures? To do this one must appreciate what sympathetic fibers reach the heart and could be utilized by afferent stimuli. We know from the work of Cannon and his pupils that sympathetic fibers extend from the heart to the central nervous system, from the first dorsal to as low as the fifth or possibly the seventh dorsal sympathetic ganglion. We also know from the work of Langley, Gaskell and Ranson that the cervical sympathetic system has no sensory fibers above the cervical ganglia. Weighing this information in relation to the surgical procedures outlined above, we must interpret relief from simple superior cervical ganglionectomy as due to the effect upon the vessels supplying the heart. We know from adequate studies and surgical observations that all vessels are sensitive, and there is proof that the sensation is carried in sympathetic fibers. We also know that these fibers control vasomotor tone in relation to the coronary vessels, however, there is no general agreement on their function as vasoconstrictors. It may be that Coffey and Brown, by excising the superior cervical ganglion merely stabilized the coronary tone for the time being, and that this explains their favorable results.

When we come to interpret the results of the Jonnesco procedure, which may produce both a motor and a partial sensory effect, or the results accruing from cutting the white ramus to the upper two dorsal ganglia, or from injecting alcohol

in order to interrupt these same conduction fibers, it is clear that if all connections with the heart are to be done away with we must extend our procedure from the first through at least the fifth dorsal level. Why, then, have favorable results been obtained? We can only state that this question cannot as yet be answered satisfactorily.

My own experience in this field comprises a considerable number of surgical attacks upon the sympathetic apparatus in the neck and upon the upper two dorsal ganglia. I have never been convinced that the relief afforded by such a procedure was complete or lasting. It is certain, however, that it has been satisfactory in a high percentage of cases. If we consider the mental as well as the physical anguish of patients with true angina pectoris, and remember that their lives are chiefly given over to waiting for the next attack, we must acknowledge that this procedure is highly desirable.

* * *

This short recital of a few methods for relieving pain emphasizes the inadequacy of our therapeutic measures. At the same time, it is apparent that when a direct attack upon a lesion causing pain is impossible, there are at least two alternate methods of possible relief,—one through section of some part of the somatic, and the other through a similar procedure on the autonomic nervous system,—which permit us to offer some help to our patients.

cedure in certain cases of widespread spinal involvement.

VISCERAL PAIN

Those who walk in this field still tread a mysterious pathway, and it may be well to restate certain accepted principles

1 The internal viscera are sparsely supplied with sensory neurons

2 The internal viscera are liberally supplied with fibers from the sympathetic or parasympathetic systems

3 The internal viscera are relatively insensitive.

4 We must conceive as an *adequate stimulus* new factors, quite different from those we commonly consider as giving rise to pain. This point requires elaboration, since progress will be difficult unless the new concept is clear to us. Thus, the internal viscera are as a rule insensitive to cutting and burning but are sensitive to changes in tension. This should have been suspected earlier on teleologic grounds alone, since an internal viscus would not be exposed to cutting or burning but would constantly undergo a shifting tension. But this doctrine of an adequate stimulus is not in itself final for visceral pain as related to special nerve fibers, for we see examples of pain from the stimulus of highly specialized nerves, such as pain in the eye from sudden exposure to intense light.

5 The sympathetic nervous system has both afferent and efferent pathways. The afferent fibers appear to pass from the viscera to the cord straight through the paravertebral ganglia without synaptic connections, entering the cord by the white rami of the spinal nerves and terminating in its gray matter. Efferent neurons in the spinal cord emerge with the ventral root and pass by way of the white rami to the sympathetic ganglia. Thus the white ramus constitutes the sole motor connection between the spinal cord and the sympathetic trunk.

6 Certain experiments, notably those of Davis and of Weiss and Davis, indicate that the somatic sensory apparatus must be intact for the perception of pain, even if we are satisfied that the original impulse travels by way of the sympathetic system. The pain of such an impulse, according to Davis, travels up an afferent pathway to the cells in the gray matter, along an afferent pathway to the paravertebral sympathetic ganglion, and from this synapse outward to the periphery, where a change occurs that stimulates the peripheral sensory nerve ending, from it the impulse passes back to the cord and upward to the cerebral centers, where pain is recognized.

7 The connections of the sympathetic nervous system afferent fibers in the cord are still unsatisfactorily demonstrated.

Two of the most important procedures for the relief of visceral pain concern the alleviation of pelvic pain and that associated with angina pectoris.

Relief of pelvic pain by sympathetic neurectomy
In 1899 Jaboulay discussed operation on the sacral sympathetic nerves for dysmenorrhea, but the operation was not popularized until Cotte's article in 1925. The procedure involves the removal of the superior hypogastric plexus and the presacral nerve. This plexus and nerve represent part of a lower splanchnic system deriving fibers from the aortic plexus, which is formed by preganglionic fibers from the celiac ganglion and lumbar trunks. The presacral nerve is thus comprised of postganglionic fibers which supply the bladder, rectum and part of the pelvic genitalia. Removal of the presacral nerves and associated fibers, with or without partial denervation of the 4 or 5 cm of iliac arteries, has been carried out largely by gynecologists, but also by neurosurgeons, in an attempt to relieve the pain of inoperable cancer and chronic painful infection in the pelvic viscera. Learmonth has paid particular attention to the results in this field. The operation consists in opening the peritoneum over the bifurcation of the iliac arteries and cleaning out all the fibers found in this triangular area. The operation has been loudly acclaimed by many gynecologists, but in our hands has not given more than 50 per cent of good results. Learmonth has had some satisfactory results in the relief of pain of intractable cystitis and in inoperable cancer of the bladder. But Chievitz* of the Finsen Institute in Copenhagen and others have found that the procedure is by no means so reliable as chordotomy, and have abandoned its use in cancer. Presacral neurectomy is followed by little disturbance of function except for sterility, though not impotence—in man. There is no alteration of the normal menstrual cycle, and pregnancy is not affected.

Relief of Pain in Angina Pectoris by Procedures that Interrupt the Sympathetic Pathways
This constitutes perhaps the earliest attempt to interrupt afferent impulses over the autonomic nervous system. It began with a suggestion made by Francoir-Franck in 1899, but was first practiced by Jonnesco in 1916. The original procedure was elaborate, consisting in the removal of the three cervical ganglia and the stellate or first dorsal ganglion on both sides. Chiefly because of the technical difficulties, and in spite of the fact that Jonnesco's first case presented a most satisfactory result, the operative

*Lecture before the Society for Clinical Surgery July 1937

in the hypothalamus seemed to lack the necessary finesse, Hess² has worked out a precise method for stimulating the various structures of this region. By his method he obtained in animals marked decrease and increase in blood pressure and heart rate, changes in the frequency and amplitude of respiration, production of salivary flow, deglutition, vomiting, defecation and micturition, changes in the width of the lids and pupils, the nictitating membrane and the secretion of tears, and atony and increase in tone of the muscles. Sleep was never produced by stimulation of the hypothalamus, but was regularly obtained by stimulation of the confines of the subthalamus and thalamus.

Action Potentials of the Brain

From study of the action potentials of the brain in 23 persons, Davis and Davis³ conclude that different people show different patterns of activity but that each reproduces his own characteristics. The individuality is not completely like that of a fingerprint, for cerebral activity is labile and dynamic, and the characterization is essentially statistical. The cortical electrogram apparently conforms to the biologic law of similarity of identical twins. Whether this is an organic hereditary feature is not known.

Walter⁴ studied the electroencephalograms of 7 cases of brain tumor before and during operation. Large, slow waves involving the whole cranium were observed when the patients were under ether and in cases of increased intracranial pressure. After reduction of this increased pressure the slow waves were restricted to the areas of the tumor. Localization by the study of the slow waves is possible only when the tumor involves or affects the cortex itself, but the waves do not arise from the tumor but from the cortex. Although the region of the tumor was found in 4 cases, this method of study can be only supplementary to the other diagnostic procedures.

Experimental Catalepsy

Ingram, Barris and Ranson⁵ were able to produce transient and prolonged catalepsy (plastic rigidity of the muscles) in cats by means of experimental lesions in the hypothalamus. Catalepsy lasted from seven to thirty days. In some cases lesions involving the caudal part of the hypothalamus and the upper part of the mesencephalic tegmentum resulted in a syndrome characterized by initial somnolence, persistent loss of motor initiative, marked disinclination to walk, acceptance of passively induced poses, indisposition to eat when hungry and vacuity of expression. Many animals showed a suppression of emotional reactions. Study

of the experimental lesions indicates that the symptoms were caused by damage to some structure or structures in the neighborhood of the mammillary bodies, such as the posterior hypothalamic nucleus, the supramammillary area, the lateral hypothalamic area and the region just caudal to the mammillary bodies.

DIAGNOSTIC STUDIES

Sense of Smell

Elsberg⁶ has carried out extensive quantitative studies on the physiology and pathology of the olfactory sense by means of a special technique, in which blast and stream injections of coffee or citral are made into the nostrils at a known volume rate and pressure. The duration of olfactory fatigue was found to depend on the number of blast injections, the frequency of injection and the volume of odor injected in each blast. The minimum identifiable odor (MIO) is also an important figure representing the smallest number of cubic centimeters of the odorous substance required for identification when injected into one nasal passage. In a clinical application of these tests on 47 verified cases of brain tumor, in or under the frontal lobes, Elsberg¹⁰ was able to localize the growth in 46 instances. In 25 of the patients the tumor was extracerebral and lay underneath one or both frontal lobes. In these cases the MIO was elevated on one or both sides, while the duration of fatigue produced by stream injection was not prolonged beyond the normal. In 11 patients the growth was within the substance of one or the other frontal lobe, in these the MIO was elevated on the side of the tumor and the duration of fatigue was prolonged on the same side. In a patient with an intracranial tumor, in whom the MIO was elevated but the duration of fatigue was not prolonged, the growth was situated underneath the corresponding frontal lobe. The author concludes that the tests of olfactory acuity and olfactory fatigue by blast injection and stream injection of odor are of value for the localization of tumors in or under the frontal lobes.

Value of Hyperpnea in Diagnosis of Certain Nervous Conditions

This test has been carried out by Massion-Vernory¹¹ as an aid in the anatomical location and evocation of signs and symptoms in certain nervous diseases. He found the test positive in 11 per cent of cases of cryptogenic epilepsy and in 37 per cent of cases of organic epilepsy. He was able to precipitate a convulsion after seventeen minutes in a patient who showed no signs of tumor. In this case the convulsion pointed to a focal

PROGRESS IN NEUROLOGY IN 1936

JULIUS LOMAN, M.D.*

BOSTON

THE literature in the field of neurology during 1936 contains many topics of both physiological and clinical interest. Investigations on the complex functions of the hypothalamus continue unabated. From many laboratories the study of cerebral activity, both normal and abnormal, by means of electroencephalography is yielding interesting and valuable information. Elsberg's quantitative tests of the olfactory sense appear to be of definite help in the localization of lesions of the frontal region. Many other aids in diagnosis of neurological syndromes are described. No unusual therapeutic advances are reported.

PHYSIOLOGIC AND PATHOLOGIC STUDIES

Relation between the Cerebrum and the Cerebellum

The experiments of Aring and Fulton¹ throw light on the physiological relation between the frontal lobes and the cerebellum—two parts of the brain which may be confused in the localization of brain tumor. The authors have demonstrated that complete decerebellation in monkeys results in tremors in the head, hands and legs, the tremors being restricted to voluntary movement. Hypotonia, a symptom usually ascribed to cerebellar disease, was never observed, nor was flaccidity after complete removal of the cerebellum. Following severance of the contralateral cerebellar peduncles and removal of the excitable regions of the cerebral cortex (Areas 4 and 6a), ataxia associated with voluntary movements in the affected extremities was abolished. When the premotor cortex (Area 6a, upper part) was removed subsequent to severance of the contralateral peduncle the cerebellar signs were accentuated. On the other hand, the cerebellar disturbances were temporarily abolished and permanently depressed when unilateral extirpation of Area 4 was done subsequent to a contralateral cerebellar lesion. From these observa-

tions the authors conclude that the premotor cortex is the part of the frontal lobe most intimately concerned in compensation for cerebellar deficit.

Hypothalamus—Physiology

Having produced minute lesions in cats with the Horsley-Clarke apparatus, Frazier, Alpers and Lewy² concluded that mesially placed bilateral lesions on the floor of the third ventricle result in complete loss of temperature control and that laterally placed lesions, whether bilateral or unilateral, cause only transitory and fleeting disturbances of temperature regulation. The vital area for temperature regulation in the hypothalamus is in the floor of the third ventricle, corresponding to the anterior hypothalamic nucleus in cats and to the substantia grisea in man.

That the hypothalamus is important in controlling temperature is supported by the findings in 2 cases reported by Alpers.³ Temperatures of 106°F and 107°F respectively occurred just before death in these patients, both of whom had been operated on for suprasellar cysts. Autopsies showed in each case destruction of the floor of the third ventricle, especially in the substantia grisea area.

Confirmation that the hypothalamus is a sympathetic center was shown by Crouch and Elliott,⁴ who utilized electrical stimulation of that region of the brain in twenty cats. The greatest rises in blood pressure were obtained by stimulating the anterior and lateral hypothalamic nuclei. Changes in respiration of various types were obtained, especially when the anterior, lateral and posterior hypothalamic nuclei and the lateral tegmental nucleus of the mesencephalon were stimulated. Dilation of the pupil was induced by stimulating the whole hypothalamus, but was best obtained from the lateral area.

Because previous methods in localizing centers

*Instructor in neurology Tufts College Medical School. Associate visiting neurologist, Beth Israel Hospital.

Lennox, Gibbs and Gibbs¹³ have also demonstrated that electroencephalography is an aid in the evaluation of the various means of treatment, for example, pentobarbital and sodium bromide prevent or alter the pathologic activity associated with a seizure. In doses which are sufficiently large to modify the electrical activity during normal periods, these drugs prevent or modify the activity associated with a seizure of petit mal.

Surgical Therapy of Epilepsy

The surgical therapy of epilepsy is discussed by Penfield.¹⁹ In idiopathic epilepsy, removal of the sympathetic nerves which follow the arteries to the brain has been attempted, but the results have been disappointing. Penfield states that there is no proof that vasomotor phenomena actually cause the attacks. Removal of the carotid body and denervation of the carotid sinuses should be carried out only when a specific hyperactivity of the carotid sinus exists. Subtemporal decompression is often adequate to correct rare cases of subdural exudations. Penfield finds that following head injury epilepsy is ten times more frequent in cases in which the dura is lacerated. In these instances it is probable that the seizures result from subsequent formation of a meningocerebral cicatrix. Progressive contracture may be followed by convulsions as long as from fifteen to twenty years after the injury. Clean removal of such a scar without subsequent cicatrization, is possible. Of 22 such cases operated on, 46 per cent showed freedom from attacks and 33 per cent showed marked improvement in a five-year period.

MIGRAINE

Further favorable results with ergotamine tartrate are reported by O'Sullivan,²⁰ who followed 89 patients who had experienced over a thousand episodes. In only 8 did the drug fail to relieve the attacks either completely or partially. Ten other drugs failed to relieve them. The author found that the intramuscular route was the most effective. A dose of 0.25 mg is sufficient for an initial injection, to be repeated in two or three hours if no relief is obtained. For oral use the dose is 1 mg. For the best results the drug should be given as early in the attack as possible. Untoward effects of the drug, such as nausea and vomiting, may be relieved by a simultaneous injection of atropine (1/100 gr) or calcium gluconate intravenously. O'Sullivan's experience with ergotamine in migraine coincides with that of Lennox, von Storch and Solomon,²¹ who found the drug effective in aborting individual migraine headaches in about 90 per cent of cases. Of 46 patients having non-migrainous headaches, 15 per cent were relieved, 63 per cent were unrelieved and 22 per cent were

made worse. Of 38 persons without headache who were given the drug, 16 per cent developed headache.

MYOPATHIES

Myasthenia Gravis

The pathologic physiology of myasthenia gravis is considered by many a deficiency of acetylcholine liberated at the myoneural junction or an increased destruction of acetylcholine by cholinesterase, with a resulting disturbance in normal contraction of muscle. If this is so, the efficacy of prostigmin is probably due to a destruction of the cholinesterase, which enhances the effect of acetylcholine produced in the body. In addition to the effectiveness of prostigmin, temporary amelioration of symptoms is obtained by glycine, ephedrine or benzedrine, and potassium chloride, the latter being given in 3-gr doses four times a day at two-hour intervals. Although prostigmin may cause some relief of muscular weakness in diseases other than myasthenia gravis, the amelioration in the latter disease following its injection is so striking that Viets and Mitchell²² find it a useful test in differentiating the disease and other conditions in which muscle strength is greatly impaired.

According to Norris,²³ changes in the thymus gland occur frequently in cases of myasthenia gravis, gross and pathologic alterations having been reported in 50 per cent of autopsied cases, including 2 of 4 cases observed by him. Various degrees of epithelial hyperplasia are found, when extreme it forms a localized and often encapsulated tumor-like mass, with obliteration of the usual lobular structure of the thymus. Norris believes that myasthenia gravis is best regarded as a disturbance of the neuromuscular mechanism, possibly on an endocrinal basis, rather than as a primary disease of the striated musculature or as one following metastases from a malignant thymus. Muscle lymphorrhagia (collections of lymphocyte-like cells in the muscles) appears to be a characteristic lesion of myasthenia gravis, having been found in two thirds of Norris's cases.

Muscular Dystrophy

The therapeutic results of glycine in 300 cases of muscular dystrophy hardly exceed those obtained from other forms of therapy, particularly pilocarpine-epinephrine, according to a survey of the literature made by Braestrup.²⁴ He treated 5 patients with muscular dystrophy, 4 with neurologic diseases affecting the muscular system and 4 with normal muscular systems. Fifteen grams of Merck's glycine was given twice daily in every case. In 1 of the 5 cases of dystrophy an undoubted improvement occurred, no benefit was observed in the others or in the neurologic cases. Increase

lesion in the right frontal area. Hyperpnea was also useful in bringing out pyramidal tract signs, such as in a case of cerebral thrombosis which showed normal reflexes before the test. The classical signs of Parkinsonism were also increased by hyperpnea in a large percentage of cases. The same was true of the signs of Sydenham's chorea. The test may also help to confirm the diagnosis of multiple sclerosis, of syringomyelia and of combined-system-disease.

Cerebral Angiography

By means of injecting thorotrast into the common carotid artery, Moniz^{12, 13} has made more than 700 cerebral angiographies with no mishaps. He has refined his technic so that he is able to take arteriograms and phlebograms, including those of the cranial sinuses, in rapid succession. In order to outline the vessels in the posterior fossa, Moniz injects the subclavian artery. In the presence of lesions which compress neighboring vessels, definite distortions of the vascular tree are observed. For example, lowering of the carotid trunk may be diagnostic of a frontal lobe tumor, while elevation may be due to chiasmal tumors. Various other specific distortions of the vascular tree are described, being due to lesions in the posterior part of the frontal lobes or tumors of the parietal lobes, anterior temporal lobe or cerebellar pontine angle. By means of angiography, aneurysms and angiomas are diagnosed preoperatively. Three types of angiomas can be identified: arterial, venous and arteriovenous.

Diagnosis of Tumors of the Corpus Callosum by Encephalography

Of a series of 3000 air studies made by Dyke and Davidoff,¹⁴ a diagnosis of tumor of the corpus callosum was made or suggested in 8 cases. Three cases were verified by necropsy, and in 2 diagnosis was confirmed by operation. Since there is no characteristic neurological syndrome by which the diagnosis can be made, the encephalographic evidence pointed out by these authors is of definite aid. The characteristic features of this condition as seen in the encephalogram are as follows: separation and asymmetrical distortion of the lateral ventricles without displacement of the ventricular system as a whole to either side, a sharply circumscribed defect in the dorsal margin of one or both lateral ventricles, occasional failure of one lateral ventricle to fill with gas, distortion of sulci and convolutions on the medial aspect of the brain, and deformity or obliteration of the dorsal and rostral portions of the fourth ventricle. The authors also point out the differential signs of other lesions which resemble tumors of the corpus callosum.

Changes in Physical Signs in Cerebellopontine Angle Tumor Following Lumbar Puncture

Helfer¹⁵ reviewed 16 cases of acoustic tumor in which a lumbar puncture had been done. In 10 there was found to be an increase in physical signs after the removal of fluid. The author recommends that in cases of unlocalized lesions in which spinal fluid is removed the patient be re-examined for more definite or new signs after the puncture. An increase in signs following lumbar puncture has also been noted in extramedullary cord tumors.

EPILEPSY

Physiology and Pathology

On the basis largely of personal experience, Lennox¹⁶ discusses the physiologic alterations of the body which may modify the frequency or severity of epileptic attacks. The induction of alkalosis by means of hyperpnea or by ingestion of large amounts of alkali tends to precipitate attacks, whereas acidosis diminishes the spells in certain individuals. The state of water balance in the body is also an important factor. The theory of vascular spasm is open to serious criticism, since records of patients taken immediately before and during spontaneous and induced seizures showed no decrease in cerebral blood flow. The author's experiments also show that during seizures there is no interference with the oxygen consumed by the brain. An acute decrease in the oxygen supply, however, may precipitate a seizure and an acute increase may inhibit it. The marked changes in the electrical potentials in the brains of epileptic patients and in those of normal individuals during the induction of alkalosis by hyperpnea, of anoxemia by breathing nitrogen, or of cerebral anemia, indicate that knowledge of the pathogenesis of epilepsy rests on ascertaining the physicochemical processes involved in the electrical activity of the neuron.

Gibbs, Lennox and Gibbs,¹⁷ experimenting with electroencephalography, find that the characteristic three-a-second wave and spike pattern, which they had previously described, is pathognomonic of attacks of petit mal, and that furthermore the frontal lobe is more intimately connected with the source of pathologic electrical activity associated with petit mal than is any other cortical area accessible from the surface of the head. That the technic used by these authors is adequate in localizing the region of a disturbance in an attack of grand mal was demonstrated in a patient whose attack began with a right Jacksonian seizure; the abnormal electrical activity appeared in the record from the left motor cortex before it appeared in the record from the right cortex.

Reduction of Cerebrospinal Fluid Pressure by Certain Solutions

In a study on the relative values of caffeine, hypertonic dextrose and saline solutions in reducing the cerebrospinal fluid pressure in normal and in neurologic cases, Blau²² comes to the conclusion that saline solutions are the most efficacious. He found that hypertonic dextrose solution caused only a temporary fall in pressure, and in only some of the cases. The effect of caffeine in depressing the pressure was also transient. Saline, 100 cc of a 15 per cent solution, caused a fall in pressure in all cases, persisting for the full length of the experiment. No deleterious effects were observed.

Effect of Blood in the Subarachnoid Space on the Cerebrospinal Fluid Pressure

As a result of their experiments on dogs, Parker and Lehman²³ found that in lacerations of the brain the cerebrospinal fluid pressure varies directly with the amount of blood that escapes into the subarachnoid space, and not with the amount of bleeding within the cerebrum. This is probably due, the authors believe, to the increase in osmotic pressure of the fluid resulting from the introduction of blood proteins.

AFFECTIONS OF THE MENINGES AND SKULL

Spinal Arachnoiditis

This condition, which is usually diagnosed as cord tumor, is described by Elkington,²⁴ who analyzed 41 cases. The etiology is very obscure. Of 41 patients, 18 had no previous illness or injury which could be found to be related to the spinal condition. Of the remaining 23, a history of spinal trauma was obtained in only 9, in 3 cases the meningeal changes were confined to the neighborhood of the damaged vertebrae, in 3 cases infection aggravated the trauma, 8 cases showed a history of severe infection, including in 2 of them meningococcus meningitis. A history of syphilis was obtained in 4 men. Any part of the cord or cauda equina may be involved either focally or diffusely. The onset may be rapid or gradual. At the onset either pain of various degrees may occur, or as in many cases, the first symptoms may be those of spinal cord compression. The signs are essentially similar to those found in cord tumor. In 10 cases some abnormality of the spine was detected clinically, either tenderness on pressure or percussion over the affected area, or spinal rigidity. Complete block was found in 1 case, a partial block in 2. The total protein was estimated in 21 cases: it was normal in 11, slightly elevated in 4, and in 5 greatly elevated, the latter ranging between 110 and 200 mg per cent. The prognosis is grave, but least so in cases oper-

ated on early, before irreversible changes have occurred in the cord itself. There was a satisfactory outcome in 7 of the 24 cases in which the subsequent course was known.

Selinski²⁵ has reviewed 8 cases of disseminated spinal arachnoiditis. A variety of associated conditions suggests that the disturbance is not a specific response, but that a variety of agents may produce a reactive inflammation of the pia arachnoid. The author states that of the nonsurgical measures high voltage roentgen therapy gives the best results.

Meningococcus Meningitis

Hoyne²¹ states that in the treatment of meningococcus meningitis the intravenous administration of serum or antitoxin is more efficacious than is the intraspinal route. Among 66 patients who received no intrathecal therapy the mortality rate was less than 12 per cent, in contrast to from 35 to 90 per cent when intraspinal treatment was used. For intravenous use the serum or antitoxin is diluted in 10 per cent dextrose or physiologic salt solution of at least twice the volume of the medicament, to which from 5 to 15 minims of epinephrine has been added. The mixture is kept at body temperature, and is given by gravity at the rate of about a drop a second. The dose of the serum is from 150 to 300 cc. an injection depending on the patient's age. Hoyne prefers Ferry's antimeningococcic antitoxin, from 50,000 to 100,000 units being given at a time. He believes in the superiority of intravenous over the intrathecal treatment, on the assumption that meningitis is a bloodstream infection with an accompanying toxemia, rather than a disease process localized in the central nervous system.

Treatment of Brucella Meningitis

Poston and Smith²² report 2 cases of this type of meningitis, which they treated intrathecally with fresh human immune serum. They describe a special technic which enabled them to isolate the organism in the spinal fluid. They state that *Brucella* infection should be suspected in cases of atypical meningitis. It can be treated by human serum obtained from persons who have been actively immunized by *Brucella*, or possibly from convalescent patients who have high agglutinating titers in their blood serums for the specific organism isolated. Patients who have no agglutinins for *Brucella* in their blood after recovery should be immunized with their own organisms so as to prevent an occurrence of the infection.

Calvarial Hyperostosis

Moore²³ has found various types of thickening of the calvarium in a study of several thousand

in the creatinuria occurred in all the cases following the administration of glycine, indicating that such a change is not specific for dystrophy

DYNAMICS OF THE CRANIOVERTEBRAL CAVITY

Physiology and Pathology

By the technic of jugular and carotid punctures and Gibbs's thermoelectric blood flow method, Loman and Myerson²⁵ have investigated some of the dynamic phenomena occurring within the human craniovertebral cavity. In contrast to the orthodox statements made regarding the physical make-up of the cavity the authors, after stressing the relative ease in which dynamic conditions on one side of the cranial and vertebral cavities are reflected to the other side, mainly by virtue of the changes occurring in the venous system, prefer to designate the craniospinal container as semirigid. They give the following summary of intracraniospinal pressure relations and changes in blood flow and gaseous metabolism of the brain under normal and abnormal conditions

(1) The cerebrospinal fluid pressure directly follows either a change in cerebrospinal venous pressure or a change in caliber of the cerebrospinal veins. The cerebrospinal fluid pressure is only indirectly related to changes in arterial pressure. Thus, a rise in arterial pressure does not affect the cerebrospinal fluid pressure unless the venous pressure, as a result, becomes increased. Studies on postural alterations particularly stress the direct relation between cerebrospinal fluid and venous pressure. Under ordinary physiological conditions, the venous pressure may be considered the chief factor in affecting the cerebrospinal fluid pressure. It is only under unusual conditions, such as severe metabolic disturbances, or under such conditions set up by injections of hypotonic or hypertonic solutions, that osmosis plays an important role in changing cerebrospinal fluid pressure.

(2) The cerebral blood flow is related to two important factors (a) the arterial pressure and (b) the caliber of the cerebral vessels. Thus, a rise in general arterial pressure results in an increase in cerebral blood flow, unless there is an associated compensating cerebral vasoconstriction. Again, cerebral vasodilatation is followed by an increased blood flow through the brain unless there is an accompanying marked fall in arterial pressure.

(3) During change in posture from the horizontal to the upright, there is a fall in carotid pressure which is kept within normal limits, probably mainly by the vasomotor system. Associated with this fall in pressure, there is a diminished cerebral blood flow and a greater uptake of oxygen per unit of blood by the brain, as compared with those maintained in the horizontal position.

(4) In individuals who have unstable vasomotor mechanisms or arteriosclerosis, the assumption of the upright position may throw an overwhelming burden on the cerebral circulation, so that the carotid pressure and cerebral blood flow fall abnormally. As a result, there is a relative cerebral anoxemia with the production of cerebral symptoms, reaching their acme in syncope or convulsions. The administration of vasodilator drugs when combined with upright tilting in normal persons may produce similar phenomena.

(5) The response of the cerebral circulation to the administration of drugs depends upon the complex pressure flow relation between the cerebral and general circulations. Probably the drug used in this study that was most dramatic in its effect was insulin. Moderate to large doses of insulin not only deplete the sugar in the blood, but may also produce a relative cerebral anoxemia, which probably explains the neurological symptoms in insulin hypoglycemia. That a relative cerebral anoxemia occurs during insulin hypoglycemia is indicated by the fact that although the blood flow through the brain tends to be diminished, there is a diminution in oxygen uptake by the brain as measured by the carotid jugular difference in oxygen.

Von Storch,²⁶ in a study of craniovertebral dynamics, has made observations regarding some phases of the normal dynamics of the craniovertebral cavity which are similar to those of Loman and Myerson, and has also commented on the technic of encephalography. He states that replacement of cerebrospinal fluid by syringe through a single lumbar puncture produces alternate elevation and depression of the fluid pressure. Simultaneous replacement of fluid prevents these alternations and minimizes the patient's unfavorable reactions. When the fluid has been completely replaced by gas, the ventriculosubarachnoid space is a gas-filled system in which pressures at all points are equal, irrespective of position. The lumbar subarachnoid pressure in such a system therefore remains the same whether the patient be sitting or recumbent, and consequently the intracranial pressures remain unchanged. The production of a final lumbar subarachnoid pressure, after complete replacement of cerebrospinal fluid by a gas, which approximates the normal lumbar cerebrospinal fluid pressure for that patient when recumbent, is not dangerous. It results in excellent roentgenograms under normal pressure-volume relation, and does not increase the patient's reaction. It is possible to introduce a volume of air at room temperature greater than the volume of cerebrospinal fluid removed without significantly increasing the intracranial pressure. The introduction of a volume of air greater than the volume of fluid it replaces increases the reliability of the roentgenograms. Subsequent to encephalography, after the manner outlined, the cerebrospinal fluid pressure is not increased above its normal value. Von Storch further points out that alternate replacement of cerebrospinal fluid by a gas through a single aperture very probably produces alternate vasoconstriction and vasodilatation of the cerebral vascular bed with hyperemia, edema, hemorrhage and severe reactions. Furthermore, the reactions subsequent to encephalography are not due to increased intracranial pressure but quite likely to shock and meningeal irritation.

areas, because of the rotation in the position of the brain produced by the blow and maintained by the adhesion. Two methods for injecting air, which reaches the subarachnoid and finally the subdural space about the involved area, are described. The technic is so devised that little or no air enters the ventricles. If sufficient air is injected, the brain, which is shrunk because of the collapse of the ventricles, pulls away from the overlying dural covering, with considerable traction due to its own weight. Of 25 cases so treated, 60 per cent were completely cured.

VASCULAR CONDITIONS

Intracranial Aneurysms

In a study of 31 cases of intracranial aneurysms Robertson³⁹ observed that the onset occurred under varying conditions, sometimes during exertion, sometimes during sleep. The ages ranged from sixteen to fifty-five. Fourteen patients survived. In some cases death occurred within twenty-four hours. Of the aneurysms definitely located at autopsy, 6 were on the middle cerebral artery, 3 near its origin and 3 near the lateral sinus, 3 were at the junction of the anterior communicating and the anterior cerebral arteries, and 2 somewhat more peripherally on the anterior cerebral artery. Aneurysms are sometimes multiple. They are more prone to develop in cerebral than in systemic vessels because the former are larger and thin-walled and bear high pressure, they are poorly supported, sometimes the paired vessel in the circle of Willis is aplastic, subjecting its fellow to greater strain. Their treatment is unsatisfactory.

The diagnosis is often difficult until rupture has occurred. Thorpe and Clegg⁴⁰ report a case in which autopsy revealed four aneurysms on the circle of Willis, which were of considerable size but had given no diagnostic symptoms during life.

In cases of aneurysm of the intracranial portion of the internal carotid artery, as shown in a review of 29 cases from the literature and 8 cases observed by McKinney, Acree and Soltz,⁴¹ diagnosis can be made by x-ray from the following findings: (1) calcification, forming a curvilinear shadow, with the convexity superiorly placed and slightly to one side of the sella turcica, (2) unilateral erosion of the sella turcica, (3) enlargement of the sella turcica, (4) unilateral enlargement of the optic foramen and superior orbital fissure, (5) erosion of the margins of the carotid canal, and (6) displacement of the pineal gland. Clinically the syndrome consists of exophthalmos and a partial or complete involvement of the second, third, fourth and fifth cranial nerves on the side on which the aneurysm exists. The third and fifth cranial nerves are always involved, and the others commonly

Purpura Hemorrhagica with Intracranial Hemorrhage

According to Garvey and Stephens,⁴² the frequency of sudden and often fatal intracranial hemorrhage in patients with purpura hemorrhagica has been underestimated. Of 30 cases of purpura which they observed, 7 of the 10 deaths followed intracranial hemorrhage. The histories preceding the onset of the hemorrhage were not significant. Bleeding into the mucous membranes was a common feature; all had hematuria, tarry stools and retinal hemorrhages. In 5 cases, in which necropsy was done, subdural or subarachnoid hemorrhage associated with bleeding into the brain substance was found. The commonest type of bleeding into the central nervous system is capillary-ring hemorrhage (brain purpura). Clinically the hemorrhage is associated with sudden hemiplegia, signs of subarachnoid hemorrhage, or coma and convulsions. The prognosis is grave and the treatment unsatisfactory.

ENCEPHALITIS AND ENCEPHALOMYELOPATHIES

Sequelae of Encephalitis Lethargica

The difficulty of prognosing the outcome of encephalitis lethargica of childhood is clear from Healy's⁴³ study of numerous selected cases of this disease. Thus, there was no correlation found between the intensity of the acute manifestations and the sequelae, nor was there any necessary relation between the intellectual function and the severity of the illness at the time of onset. Healy's study also substantiates the conclusions reached by others to the effect that damage to the central nervous system frequently continues long after the acute manifestations of the disease have disappeared. Because of this, "chronic encephalitis" would be more accurate than "postencephalitic sequelae."

Paroxysmal vegetative symptoms occurring as postencephalitic sequelae have been observed in 2 cases by Borremans and van Bogaert.⁴⁴ The attacks included vasodilatation with generalized sweating, tachycardia, often irregular, tachypnea or arrhythmic respiration, more or less periodic, hyperthermia, insatiable hunger and thirst, and increased abdominal peristalsis, even to involuntary evacuation.

Involvement of the Nervous System Associated with Influenza

In the course of epidemics of influenza, Laszlo and Nowotny⁴⁵ observed many cases showing mild involvement of the nervous system. While some patients developed a complete picture of Economo's encephalitis, the spinal cord and its meninges were principally involved, the lower extremities suffer-

skulls These deposits symmetrically involve the inner table of the bones or the diploe, usually in the frontal area, although the skulls are generally thickened The condition causes a symptom-complex which is as characteristic as the skiagraphy The symptoms consist of a more or less constant combination of headache, obesity or a tendency to obesity, muscular weakness and fatigability, nervousness, a tendency toward worry or depression, dimness of vision, epileptiform seizures, mental slowness to dementia, dizziness and disturbances of equilibrium and gait Sometimes there is impairment of the seventh nerve, difficulty in speech, loss of the sense of smell, dragging of an extremity and hirsutism in women Ninety-eight per cent of the author's cases occurred in women The condition does not coincide with any of the groups of osseous dystrophies, and does not appear to form part of any endocrinal disease It is a metabolic disease, in which the fat and calcium metabolism alone are at fault

Carr³⁴ studied 17 patients with varying degrees of hyperostosis of the inner table of the frontal bones, causing symptoms similar to those found by Moore Because of the high frequency of the obesity and the increase in dextrose tolerance, the author believes that many of the symptoms are metabolic in origin

TRAUMA TO THE BRAIN

Mental Sequelae Following Head Injury in Children

Very little is found in the literature regarding mental sequelae following head trauma in children Blau³⁵ gives the histories of 22 children with mental disorders following head injury Among these were 6 cases of acute psychosis, 4 of these showed bloody spinal fluid and no neurologic signs except for meningeal irritation The symptoms included acute excitement, marked impulsiveness and restlessness, complete lack of restraint, irritability and fear In 5 cases the psychosis lasted from fourteen to thirty-five days Follow-up histories obtained in 4 cases, ranging from six months to four years, failed to show significant sequelae Twelve cases in Blau's group showed chronic behavior disorder overactivity, restlessness, destructiveness, assaultiveness, cruelty to animals, emotional excitability, temper tantrums, truancy and delinquency The prognosis in most cases was poor No signs of focal disease of the central nervous system were evident Post-traumatic epilepsy occurred in 5 children The acute and chronic disorders differed only in degree and duration The syndrome is undoubtedly based upon pathologic changes in the brain, probably of a diffuse type

Brain Trauma in the Newborn

Despite the popular belief that asphyxia is frequently the cause of death in newborn children in cases of prolonged delivery, Heidler³⁶ holds that cranial injury is the primary cause Autopsies on 76 birth injuries showed hemorrhage in the subdural spaces, in the leptomeninges and ventricles, and intracerebrally In some cases tentorial tears and rupture of the pial vessels were found Asphyxia is secondary to such brain injury, according to Heidler To prevent these deaths, the author urges a shortening of the final stage of labor

Therapy of Head Injury

In discussing the treatment of intracranial injuries, Dandy³⁷ gives the following suggestions After the injury the patient should be put to bed immediately, and should not be subjected to x-ray or lumbar puncture, since these procedures are not necessary for diagnosis More important is careful observation of coma or restlessness Coma indicates increased intracranial pressure if it deepens, the pressure is increasing, if it lessens, the pressure is being compensated Restlessness shows that compensation is inadequate Morphine should never be administered Irregularity in the pulse rate and volume and a steady increase are both danger signs Dandy believes that hypertonic solutions are unsatisfactory, since they have only a temporary effect and are injurious to the brain Lumbar puncture, he feels, is also useless and results in later increase in pressure beyond the original level The only acceptable treatment, according to him, is surgery Operation is indicated at the point of breaking compensation or just beyond it Small openings in the parietal region on the suspected side are made if localized signs are present If fluid is not found, similar openings are made on the opposite side If there is no relief of pressure, subtemporal decompression is done Subdural hematoma, which develops later, is diagnosed by ventriculography Extradural hematoma, with coma developing after a free period and convulsions spreading from the face to the arm and leg, is treated by removing the hematoma and tying off the branches of the torn meningeal artery

Penfield and Norcross³⁸ describe the pathology of post-traumatic headache, and outline a special technic by which this condition is surgically relieved The authors state that the pathological basis of true post-traumatic meningeal headache consists in an intimate adhesion of the arachnoid to the dura, which causes obliteration of the dural space in a smaller or larger area The sensitive area, which is likely to be affected by this adhesion, is usually a meningeal artery in the dura, and less frequently a dural sinus Chronic pain results from pressure or traction on one of these sensitive

as generalized weakness and absence of reflexes. Such symptoms may be due to involvement of the nerves by the trichinae or a toxin elaborated by them. Dermatomyositis or periarteritis may also have to be considered in the differential diagnosis. In those cases of trichiniasis in which only the signs of polyneuritis are present, the prognosis is good. When mental symptoms or signs of focal lesions in the central nervous system are present the outlook is much more serious.

NEUROSYPHILIS

Etiology and Therapy

According to statistical reports made by Moore and Merritt,⁵² syphilis of the nervous system was considered the cause of mental disease in 9.3 per cent of the total number of cases admitted to the Boston Psychopathic Hospital from 1912 to 1934. Menninger,⁵³ in a comprehensive study of the literature on the subject of juvenile paresis, concludes that this type of syphilis occurred in less than 2 per cent of all cases of paresis and in about 1 per cent of congenital syphilis. The onset occurred in most cases around the fourteenth year in girls and around the fifteenth year in boys. Therapy in juvenile paresis is very disappointing when compared with the results obtained in adult cases.

Kemp and Menninger,⁵⁴ in an attempt to correlate the treatment of early syphilis and the incidence of neurosyphilis, studied 680 cases in a large syphilitic clinic. This study showed that of 253 patients who had received no treatment, 52.6 per cent had neurosyphilis, of 226 who received early inadequate treatment, 43.4 per cent had it, and of 201 who received adequate treatment, 16.9 per cent had it. Kemp and Menninger also found that patients inadequately treated showed a six-year reduction of the incubation period of clinical neuroles when compared with a group receiving no treatment.

Epstein, Solomon and Kopp⁵⁵ found, in a review of the literature of the results of therapy of general paresis with fever produced by diathermy and related mechanical modes of hyperpyrexia, that of 648 cases reported between 1929 and 1935, good remissions were observed in 27 per cent. Of 33 patients treated by the authors with diathermy between 1931 and 1934, 8 were improved and working, and 7 were improved but not working. Four patients, while remaining hospitalized, were known to be improved, 4 patients were living but unimproved, and 10 had died. There appeared to be a correlation between the clinical status and the reaction of the spinal fluid.

Solomon and Epstein⁵⁶ also present a series of 21 cases—19 of paresis and 2 of congenital neurosyphilis—treated over a continuous period of time by tryparsamide and subsequently given fever. These cases had previously shown unsatisfactory

responses to tryparsamide alone. All these patients responded satisfactorily both clinically and serologically to the fever therapy. The authors believe that preliminary tryparsamide injections greatly enhance the possibility of therapeutic success in the treatment of general paresis by fever, and that the improvement of the spinal fluid findings occurs sooner after fever if the patient has been prepared for the treatment with tryparsamide.

Barnacle, Ebaugh and Ewalt⁵⁷ treated one series of 30 paretics with diathermy and tryparsamide, and an equal-sized group with malaria and tryparsamide. There was no essential difference in the beneficial results, for 70 per cent and 63.6 per cent, respectively, showed improvement. There was no correlation between serologic reaction and clinical improvement.

Good results with malaria treatment are reported by Hutchings,⁵⁸ who used this type of therapy for ten years. Of 182 male paretics, 66 were much improved. Tabetics showed less encouraging results. Patients with psychoses of less than one year's duration presented the best outlook.

Cranial and Peripheral Nerves

Carotid-Sinus Nerve Involvement

The carotid-sinus nerve, a branch of the glossopharyngeal, is a depressor nerve, section of which is apt to be followed by a temporary rise in blood pressure. Bucy⁵⁹ reports 5 cases in which it was necessary to expose and section the glossopharyngeal nerve. Following the operation in 3 cases there was a sharp rise in blood pressure, which became normal within a few days. In 1 case the blood pressure rose markedly after sectioning and remained at the higher level during hospitalization.

Syncope and convulsions due to hyperactive carotid-sinus reflex have been observed by Weiss, Capps, Ferris and Munro⁶⁰ in 52 patients. The treatment of the abnormal reflex is directed toward the correction of all associated abnormalities. The administration of digitalis should be carefully watched, since it sensitizes the sinus reflex mechanism. One patient was relieved by treatment of a tuberculous gland, 1 by antiluetic treatment, 2 by correcting food deficiency and 4 by diminishing the dose of digitalis. Of 10 patients who were treated by surgical denervation within the previous two years, 8 remained free from attacks and 2 had a recurrence of symptoms.

Neuralgia

Harris⁶¹ reports that of 856 cases of tic douloureux 39 were bilateral. Of 41 patients with spastic paraplegia 7 had bilateral tics. The author believes that alcoholic injection is satisfactory for bilateral tic, even if it is necessary to perform both the injections at one sitting. If jaw droop results, re-

ing the brunt of the attack. All cases presented more or less developed symptoms of meningo-myelitis with a protracted duration. Some cases showed flaccid paraparesis and others only a slight decrease of power with pyramidal signs. Transient signs of meningeal irritation and neuritic irritation were also noted.

Mumps and Encephalomyelitis

Inflammation of the brain and the meninges in the course of mumps may be very marked, as observed by Jasinski.⁴⁰ In 1 case the meningeal symptoms were pronounced and were associated with high fever, intense headache and vomiting. The pathologic picture was that of a serous meningitis. Lumbar puncture showed a marked increase in pressure, clear sterile fluid and a high lymphocytic count—from 85 to 100 per cent. The course of the disease is stormy and short, and recovery is usual. In other cases of mumps the symptoms suggest encephalitis with involvement of the meninges.

Multiple Sclerosis

The various theories of the pathogenesis of multiple sclerosis are discussed by Brickner.⁴¹ Experimental lesions similar to those seen in the brain in this disease have been produced in animals by Ferraro, who injected small doses of potassium cyanide, and by Putnam, who used tetanus toxin, carbon monoxide and cod liver oil. Putnam believes that the resulting patchy demyelination is due to the production of venous emboli and thrombi. Rivers and Schwentker produced similar lesions by repeated intramuscular injections of alcohol extracts of brain lipoids. Brickner himself attempted to find as a cause of multiple sclerosis a lipolytic agent which might affect myelin. He found that in active phases of multiple sclerosis the degree of blood-serum esterase activity was low, whereas during inactivity it was high.

Putnam⁴² believes that the venular thromboses found in multiple sclerosis are primary and not secondary changes in the nerve tissue, and may be due to some fundamental disorder of the blood which results in clot formation in the cerebral vessels. He suggests that it may be possible to formulate a therapeutic program by lowering the level of fibrinogen by diet, by causing a decrease of platelets, or by administering an anticoagulant drug.

Nervous and Mental Sequelae in Carbon-Monoxide Poisoning

Shillito, Drinker and Shaughnessy¹⁹ have collected records covering the accidents from carbon monoxide in the metropolitan area of New York City for ten years. During this period 21,000 exposures to the gas were recorded. A search of New

York City institutions disclosed that only 42 case histories showed mental and nervous sequelae. From the histories it was evident that deep intoxication preceded all aftereffects. Artificial respiration and inhalations of oxygen and carbon dioxide had to be resorted to during treatment. Subsequent clinical manifestations were headache, dizziness, gastric distress and nausea due to cerebral edema induced by the poisonous gas. Temporary psychoses were the most frequent aftereffects of carbon-monoxide poisoning, common manifestations being confusion and loss of memory. Improvement within a few months was noted. Most of the psychotic patients were sufficiently improved in a year so that they could be paroled home. The more permanent neurologic lesions included 9 cases of muscular hypertonia (increased reflexes, ankle clonus and Babinski), 5 cases of hypertonia and some degree of peripheral neuritis (2 permanent), 4 cases of Parkinsonism (3 permanent), 1 case of Parkinsonism and some degree of peripheral neuritis, and 10 cases of peripheral neuritis. Ten deaths occurred before a complete neurological examination could be made.

Encephalopathy Following Extensive Burns

Only a few observers have been able to demonstrate involvement of the nervous system secondary to burns. Globus and Bender⁵⁰ report a case of an eight-year-old boy who received extensive second degree burns. He recovered from the shock but showed increasing evidence of toxicity. The neurological examination was negative, but the patient developed an abnormal mental state, first refusing food and defecating and voiding in bed, later he became abusive to the nurses, expressed deep resentment against his parents, and gradually became unresponsive, withdrawn and subject to attacks of deep anxiety. He often expressed a desire to die. It is interesting to note that for a time psychiatrists who examined the patient thought that his mental state was due to psychic trauma caused by the accident which had led to regression to an infantile level. A short time later the patient rapidly became emaciated, and he died about six months after admission. The brain showed many changes resembling those of multiple sclerosis. It is probable that they were caused by a toxic agent formed in the disintegrating, burned tissues.

Involvement of the Nervous System in Trichiniasis

Merritt and Rosenbaum⁵¹ report 2 cases of trichiniasis in which there were neurologic complications. The authors point out the difficulty of diagnosis. When trichiniasis involves the nervous system it may simulate polyneuritis, acute poliomyelitis, encephalomyelitis or, rarely, meningitis, although the spinal fluid is usually normal. It is difficult to explain the signs of polyneuritis, such

of vascular disease, primarily arteriosclerosis, was present in a large percentage of the cases, arteriosclerosis, however, may be the result of the diabetic factor rather than the cause of the neuropathy. Deficient dietary intake seemed of no significance, as judged by the dietary histories and the result of feeding accessory food substances. Marked improvement in symptoms and signs occurred within a few weeks in many cases, and within a few months in most.

Jolliffe, Colbert and Joffe⁶⁸ present data which tend to confirm the hypothesis that alcohol neuritis is caused by avitaminosis. The authors made a survey of 26 alcoholics with neuritis and 16 alcoholics without it. They employed Cowgill's formula which expresses the vitamin-B need as the quotient obtained by dividing the vitamin-B equivalent expressed in milligrams by the total caloric intake. Normally this ratio should be about 2. It was found that the vitamin intake was inadequate in most of the 26 patients with neuritis, but was adequate in most of the 16 without neuritis.

covery will take place because the motor roots will regenerate

Horrax and Poppen⁶² give the differential features of neuralgia affecting the head. Postherpetic neuralgia usually shows scars of herpetic vesicles involving the trigeminal nerve, and usually clears up in several weeks. The pain is not controlled by alcohol injection or posterior root section. In Sluder's or sphenopalatine neuralgia the pain is usually at the base of the nose, upper jaw and eye, radiating back to the ear and mastoid regions, and extending at times to the back of the neck, shoulder and upper extremity. Neuralgia due to involvement of the geniculate ganglion involves the sensory portion of the seventh cranial nerve, causing severe otalgia. Glossopharyngeal neuralgia involves the tonsils, pharynx and posterior part of the tongue. Pains due to sympathetic involvement are usually dull, aching, burning or elicited by pressure, and seldom follow the anatomic distribution of nerves. In mild cases of trigeminal neuralgia, inhalations of trichlorethylene are advised. Of 90 patients, nearly a half had sufficient relief so that they required no other form of therapy for as long as from six months to six years. If no relief is obtained by this treatment, alcohol injections are given. This measure is not only of therapeutic value but serves as a diagnostic test. Of 600 cases where injections were performed by the authors, the average period of relief was 14.3 months. Sensory-root operation is advised only if alcohol injection fails to give relief. It was performed on 176 patients without a single fatality, keratitis developed in 9 patients and temporary facial palsy in 6.

Treatment of Facial Paralysis

For cases of facial palsy that is complete and permanent, Davis and Cleveland⁶³ discuss two methods of surgical treatment: (1) an attempt to repair the atonic musculature by transplantation of fascia, (2) an attempt to effect an end-to-end anastomosis, or, when this is impossible because of scar and callus formation, suturing the distal end of the facial nerve and the central end of another nerve. Of the latter method, the most successful anastomosis was obtained with the hypoglossal nerve. Muscle tone and symmetry of the face quickly returned. Facial movements were at first associated with tongue movements, but after two years the patients were able to dissociate the two. Postoperative treatment consisting of mechanical devices, electrotherapy and educative exercises is also advised.

Bertola, Yadarola and Sala⁶⁴ recommend the operation of Leriche for facial palsy not amenable to conservative treatment. This consists of resection of the superior cervical ganglion, resulting in paralysis of Müller's muscle so that drooping of the eyelid occurs. Associated with the ptosis of the lid

there are enophthalmos and miosis, vasomotor symptoms and abundant salivation. Many of the symptoms gradually disappear. The tonus of the cheek improves and the nasolabial fold recovers practically its normal form. Excellent results in 3 cases are described.

Postoperative Neurologic Complications

The many neurologic conditions which may occur during convalescence from an operation are discussed by Woltman⁶⁵. The peripheral nerve disorders include neuritis of the ulnar nerve due to pressure of the arm on the operating table, peroneal palsy due to pressure on the underlying mattress or crossing of the legs, and brachial palsy in women, which may follow pelvic operation or be caused by poorly padded shoulder rests, asymptomatic cervical ribs or faulty posture during narcosis. Certain cranial nerves may be involved, notably the sixth, less often the third and fourth. The cause of the latter involvement is unknown. Before deciding on surgery the presence of deficiencies should be determined, otherwise, pathologic conditions may be precipitated. The author cites a case of a woman who since limiting her food intake because of a fecal fistula had developed combined system disease of the cord, death occurred three days after spinal anesthesia for resection of the sigmoid. Another patient after living on milk and eggs for six months developed Korsakoff's syndrome after gastroenterostomy. The various types of psychoses following operation are also discussed.

Dietary Deficiency as Etiologic Factors in Certain Neurologic Syndromes

In Perkins's⁶⁶ observation of 82 cases of neurologic conditions in which multiple neuritis was conspicuous and which included alcoholism, pernicious anemia, cancer of the intestinal tract, malnutrition and pregnancy, he found digestive disturbances constantly present. In every case a logical explanation for the lack of intake or failure of proper digestion or assimilation could be made. The varieties of clinical syndromes were very similar to those seen in such deficiency diseases as beri-beri, pellagra and sprue.

Neuritic Manifestations in Diabetes Mellitus

Jordan⁶⁷ presents findings in 120 cases of diabetes with relatively acute and usually severe neuropathy. Among 1000 consecutive cases of diabetes observed by the author, there were 25 cases of neuritis, which involved the legs in 16. Pain, paresthesia, hyporeflexia and areflexia, muscle paresis, tenderness of the nerves and muscle, hypesthesia and hyperesthesia were the most frequent manifestations. The spinal fluid contained excess protein. Hyperglycemia did not appear to be an essential factor in the production of the neuritis. Evidence

outline of the left kidney to be slightly larger than the right and low in position

On the sixth hospital day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR. CHANNING C. SIMMONS There are one or two further points I should like to know. In the physical examination no mention is made of enlargement of the thyroid or parathyroid glands. I presume they were negative. I rather question one or two statements about the bones in the x-ray examination. May we look at the films to see if the other bones are normal? The diagnosis is one of five or six conditions: (1) inflammatory condition, (2) some form of metabolic disease, (3) one of the rare skeletal diseases, (4) primary bone tumor, (5) one of the other tumors sometimes primary in bone, such as malignant lymphoma or reticulum-cell sarcoma, (6) metastatic tumor.

The possible inflammatory conditions are tuberculosis, osteomyelitis and syphilis. I think we can rule out tuberculosis. Acute osteomyelitis in a man of his age is unusual. It is also unusual to have a Brodie's abscess without more thickening of the cortex, from irritation, above and below the cavity. Moreover his blood was normal except that the white-cell count showed 79 per cent polymorphonuclears, which is high, and the monocytes were high—12 per cent.

Syphilis always has to be borne in mind. The Hinton test was negative. The syphilologists tell me that 40 per cent of the cases of tertiary bone syphilis have negative Wassermann reactions. The Hinton is of course more sensitive but not infallible. Consequently, although it is negative, syphilis has to be considered.

Metabolic disease such as Paget's disease and parathyroid disease should be considered. I should say the bones were not normal. I do not know how Dr. Holmes feels about them. Is that the x-ray of a normal humerus?

DR. GEORGE W. HOLMES I think part of the appearance is due to the fact that the film was not taken in the usual position.

DR. SIMMONS Is that not a thick bone?

DR. HOLMES Yes it is, and is somewhat suggestive of Paget's or syphilis.

DR. SIMMONS Is the appearance due to position?

DR. HOLMES I should not say that the femurs were abnormal. In this region you have a thickening of the cortex which does not indicate disease. You might get such an appearance with an old fracture. I think you can rule out an inflammatory condition.

DR. SIMMONS As regards Paget's and parathyroid disease, the blood chemistry seems to be normal. If it were Paget's disease one would expect a higher phosphatase, 4.28 units is practically normal according to the Bodansky method. One would expect it to be 8 or 10 in Paget's disease.

I think we can rule out the rare skeletal diseases. They are certainly not suggested by the x-rays.

We come down to primary bone tumor, metastatic tumor, reticulum-cell sarcoma and lymphoma. Primary bone tumor in a man of forty-three is unusual, except Ewing's sarcoma which does not originate in this situation. It is a bone-destructive tumor and is usually not situated in the center of the shaft of the bone. One has also to consider giant-cell tumor, giant-cell tumors arise at the end of the bone, not in the center, and are clear cut where they join the shaft. They expand rather than destroy the cortex. We then come to reticulum-cell sarcoma and lymphoma. The x-ray does not suggest lymphoma. Reticulum-cell sarcoma appears by x-ray as a mottling of the medulla or as a bulky tumor with bone destruction, and the films do not suggest this type.

Any malignant tumor may give bone metastases although they occur much more commonly with cancer of the thyroid or breast and with hypernephroma. This man has a tumor connected with his left kidney which apparently has given no symptoms so far as the urinary tract is concerned. He has never passed blood, and this is suggestive of hypernephroma situated at the top of the kidney. A tumor so placed does not involve the calices and therefore does not give any blood in the urine. My feeling would be that we have a metastatic tumor of the tibia, the probable origin of which is a tumor of the kidney, a hypernephroma. The x-ray is our best single method of diagnosing bone tumor but not the last word.

DR. TRACY B. MALLORY Have you anything further to add, Dr. Holmes?

DR. HOLMES I should like to confirm the statements Dr. Simmons has made. It is true when you come to look at all the bones in this patient that he has rather heavy, short bones, and it is also true that they were not adequately described in the text. Thickening in the cortex of bones, as seen in the left tibia, always makes one suspect syphilis, but this particular lesion is localized and can better be explained on the basis of an old fracture. When we come to the lesion in the shaft, it is a purely destructive process with no attempt at new bone formation. For that reason I should agree with Dr. Simmons that it is metastatic and not a primary tumor. Its location and the character of the lesion itself point to a metastatic process. In re-

TRACY B. MALLORY, M.D., *Editor*

CASE 24101

PRESENTATION OF CASE

A forty-three-year-old Italian shoemaker was admitted complaining of a tender swelling on the right leg.

The patient had been well until three months before entry when he first noted a small tender area on the medial aspect of the right tibia. The sensation was "burning" in character and the leg ached after walking. There had been no injury to this region, nor were there any other associated symptoms. The local application of various self-administered medications produced no relief. Six days before coming to the hospital the pain increased in severity, and slight swelling was noted in the area involved. There were no other significant symptoms. His weight had been stationary for three years.

The past history was noncontributory.

Physical examination showed a well-developed and nourished man in no evident discomfort. Examination of the head and neck was negative except for a pea-sized, firm, non-tender node in the right cervical region. The lungs were clear. The heart was normal. The blood pressure was 150 systolic, 100 diastolic. The abdomen was soft, and there were no areas of tenderness. A mass was felt in the left upper quadrant which extended two fingerbreadths beneath the costal margin. No notch was felt, but the edge was sharp. A rectal examination was negative. At the juncture of the middle and upper thirds of the posterior portion of the medial surface of the right tibia there was an area of roughening of the bone about 2.5 cm in diameter. The skin in this region was warm and slightly reddened, and pressure over it produced pain. The remainder of the examination was negative.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. No Bence-Jones protein was found. The blood showed a red-cell count of 6,700,000 with 86 per cent hemoglobin. The white-cell count was 8800, 79 per cent polymorphonuclears, 8 lymphocytes, 12 monocytes, and 1 eosinophils. The serum calcium was 9.52 mg per cent, the phosphorus 5.08 mg per cent,

and the phosphatase 4.28 Bodansky units. A blood Hinton test was negative.

An x-ray showed an ovoid area of bone destruction within the middle portion of the shaft of the right tibia (Fig 1). The lesion lay within the

Figure 1 X-ray photograph of midportions of the right tibia and fibula

marrow but involved the central portion of the cortex. The area was fairly well outlined, and there was no evidence of newbone formation or periosteal reaction. No soft-tissue mass was seen. There was a fusiform thickening of the cortex of the left tibia at the middle third of the bone. The lesion was in no way related to the lesion on the right and might have been the result of an old fracture. An x-ray of the chest showed the heart to be transverse in position, slightly enlarged, and there was calcification of the aortic knob. The lung fields were clear. An abdominal film demonstrated calcification of the pelvic arteries. The other bones exhibited no variation from the normal. The left kidney was slightly larger than the right and appeared to be displaced downward. A retrograde pyelogram showed the kidney outlines on the right side to be normal in size and position. Both psoas outlines were well visualized. The left kidney pelvis lay at the level of the third lumbar vertebra and appeared to be displaced somewhat laterally. The minor calices were well defined. The course of the left ureter was directly to the right of the lower border of the second lumbar vertebra at which point it turned sharply downward and followed its usual course. No calculi were seen. Another film showed the

was not in the kidney. As you can see from the photograph (Fig 2), which was taken after the specimen had been dissected, the tumor lay medial to and slightly above the kidney and though closely attached to it could readily be separated from it. When the sections of the primary tumor were available it was evident that it was a primary carcinoma of the adrenal. The subsequent course of the patient was a little stormy. He developed intestinal obstruction in the jejunum in the region from which the tumor had been resected, so it proved necessary to resect about 60 cm of the jejunum. He survived that and is symptom free now, just a year later.

CASE 24102

PRESENTATION OF CASE

A forty-four-year-old white Canadian lumberman entered the hospital with the complaint of progressive blindness of fourteen months' duration. Fourteen months before entry while working in the woods he suddenly developed almost total blindness. However, in about fifteen minutes his vision cleared so that he could continue his work, but he still had difficulty in seeing. Twelve months before entry the entire right side of his body suddenly became numb. He felt dizzy and fell to the ground. He felt faint but did not lose consciousness. For about ten minutes he was unable to get up and after that could not continue his work because of severe occipital headache. For the subsequent two or three days the muscles of the right side of his body were very sore. The headache disappeared but recurred for brief intervals whenever he lifted heavy objects. For the next six months whenever he looked upward he saw 25 or 30 blue balls, like bunches of grapes, and had a sensation that the "earth was going over backwards." This sensation stopped as soon as he looked down. Six months before entry his left eye became totally blind and gradually the vision of his right eye became more and more impaired until he could see only out of the nasal side of it. He also began to have severe temporal headaches lasting twenty-four hours, and the movements of his legs became clumsy and unsteady. He had no auditory, olfactory, or other cranial-nerve symptoms, and he was able to continue his work up to a short time before entry. There was no memory loss or change in habits.

He had been married for twelve years and had seven children living and well. One had died of pneumonia and three had died in infancy. He said he had had all the childhood diseases except scarlet fever and diphtheria. Twenty years before entry he had been struck by a derrick arm

on the left side of the face and knocked unconscious, but had had no cerebral symptoms following the incident. He denied venereal disease, and had had no neuromuscular symptoms except those given above.

Physical examination revealed a well-developed and nourished man in no apparent discomfort. There was slight tenderness over the right mastoid and over the occipital protuberance. His heart, lungs and abdomen were negative, and his blood pressure was 110 systolic, 68 diastolic. The right side of his face was covered with drops of perspiration, but the left side was warm and dry. The left eye was totally blind, and there was complete temporal hemianopsia of the right eye. The fundi were normal, and the disks were slightly pale. There was slight cloudiness of the left cornea. The right pupil reacted sluggishly to light and accommodation, and the left pupil showed only consensual light and accommodation reflexes. There was no diplopia, squint or nystagmus, and the cranial nerves were otherwise negative. The vibratory sense and the motor and sensory systems were normal. There was a positive Romberg and a slightly unsteady gait, but no rebound phenomena. Position sense was normal, and the finger-to-nose and heel-to-knee tests showed no incoordination. Stereognosis was normal. The reflexes were entirely negative.

The temperature was 98.6°F., the pulse 50. The respirations were normal.

The urine examination was negative. The blood showed a red-cell count of 5,250,000 with 95 per cent hemoglobin, and a white-cell count of 12,100 with 76 per cent polymorphonuclears. A lumbar puncture showed an initial pressure of 100 with normal dynamics. The fluid was clear and colorless, contained no cells, and showed a total protein of 56 mg and a sugar of 66 mg per cent. The goldsol curve was 0001221100, and the spinal fluid Wassermann was negative.

X-rays of the head showed marked thickening of the skull, prominence in the supraorbital region and in the lower jaw, large sinuses, large pachionian bodies in the frontal region, and slight increase in the convolutional markings. The sella was large, the posterior clinoids were slightly atrophic, and there was slight spreading of the anterior clinoids.

On the evening of the fifth day after entry he called the nurse and said there was something the matter with him. Immediately afterward he became stiff, pushed his right leg and arm out from under the bedcovers, and began to have rapid, violent clonic convulsions of the whole right side of his body accompanied by fine convulsions of the

gard to the kidney, any lesion which displaces the kidney and its pelvis downward, as this does, in all probability is either in the kidney itself or retroperitoneal, very close to it. Lesions in the abdomen do not displace the kidney downward. I think it is perfectly safe to say that the mass causing the displacement is part of the kidney or in some way connected with it. Tumors of the cortex of the kidney as a rule involve the pelvis. They cause some distortion of the pelvis—more distortion than is seen in this case. But you can have a considerable tumor without distortion of the pelvis. A tumor large enough to displace the kidney downward should give evidence of involvement of the pelvis. The character of the lesion in the bone is quite typical of metastasis from a kidney tumor.

DR MALLORY: Have you any comment, Dr Smith?

DR GEORGE G. SMITH: I do not remember seeing this case so I am not prejudiced. I should agree entirely with what Dr Holmes has said about the difficulty of assuming a tumor of the kidney cortex because, as he very well pointed out, if you had a tumor large enough to push the kidney down this far you certainly would expect to see some narrowing or abnormality in the upper calyx. So far as I can see, the outline of the kidney is fairly normal. A tumor of the adrenal could certainly push the kidney down. I suppose this is the type of case where one would be tempted to do oxygen or air insufflation of the suprarenal area. It is not entirely without danger but has been done by some men very frequently. I always thought that metastases from hypernephromas which lodged in bone were found at the ends of the bone, the theory which has been advanced being that the small emboli of tumor cells were held up at the point where the larger arteries subdivide into smaller ones at the junction between the shaft and the epiphysis. I suppose that does not hold in every case, but generally speaking if it were a hypernephroma metastasis, I would expect it to be at the end of the long bone. There has been no blood in the urine. I can see no reason to think that the kidney per se was involved except on the theory that this tumor might be a metastatic hypernephroma. There is no evidence of involvement of the kidney, the only thing being the fact that it is pushed down.

DR JAMES H. MEANS: What about the sharp edge of the tumor? What about the six and a half million red-cell count? I do not think they can be dismissed.

DR MALLORY: Apparently no attention was paid to them.

DR MEANS: I do not know of any bone lesion that gives an erythremia, but I should like to ask

you if any sort of thromboses in the bone marrow could be the cause of such a condition as this, because patients with erythremia would thrombose anyway.

DR MALLORY: I never saw gross lesions of the bone produced in that way. Only a single red-cell count was done.

PREOPERATIVE DIAGNOSIS

Metastatic hypernephroma of the tibia, right

DR SIMMONS'S DIAGNOSIS

Metastatic tumor, probably hypernephroma

ANATOMICAL DIAGNOSIS

Carcinoma of the adrenal

PATHOLOGICAL DISCUSSION

DR MALLORY: The lesion of the bone was biopsied, and a small amount of material curetted out. In the sections we found an epithelial tumor composed of fairly large cells, with prominent cell membranes and very light semivacuolated cyto-

Figure 2 Left kidney with adherent tumor of the adrenal

plasm. The appearance was so close to that of hypernephroma that I had no hesitation in making a flat-footed diagnosis of metastatic hypernephroma. That seemed to settle the differential diagnosis, and it was decided since there seemed to be a single metastasis it was worth while to go ahead and remove the primary tumor. It was done through an anterior approach by Dr Allen, who found a very large tumor lying above and closely attached to the kidney. He did not attempt to discover whether it was in the kidney but removed the tumor and kidney together. The tumor was very adherent to the jejunum and was separated with a great deal of difficulty. When the tumor was finally removed and examined it was clear that it

was not in the kidney. As you can see from the photograph (Fig. 2), which was taken after the specimen had been dissected, the tumor lay medial to and slightly above the kidney and though closely attached to it could readily be separated from it. When the sections of the primary tumor were available it was evident that it was a primary carcinoma of the adrenal. The subsequent course of the patient was a little stormy. He developed intestinal obstruction in the jejunum in the region from which the tumor had been resected, so it proved necessary to resect about 60 cm. of the jejunum. He survived that and is symptom free now, just a year later.

CASE 24102

PRESENTATION OF CASE

A forty-four-year-old white Canadian lumberman entered the hospital with the complaint of progressive blindness of fourteen months' duration.

DR. MALLORY: I never saw gross lesions of the bone produced in that way. Only a single red-cell count was done.

PREOPERATIVE DIAGNOSIS

Metastatic hypernephroma of the tibia, right.

DR. SIMMONS'S DIAGNOSIS

Metastatic tumor, probably hypernephroma.

ANATOMICAL DIAGNOSIS

Carcinoma of the adrenal.

PATHOLOGICAL DISCUSSION

DR. MALLORY: The lesion of the bone was biopsied, and a small amount of material curetted out. In the sections we found an epithelial tumor composed of fairly large cells, with prominent cell membranes and very light semivacuolated cytoplasm.

Figure 2 Left kidney with adherent tumor of the adrenal.

The appearance was so close to that of hypernephroma that I had no hesitation in making a flat-footed diagnosis of metastatic hypernephroma. That seemed to settle the differential diagnosis, and it was decided since there seemed to be a single metastasis it was worth while to go ahead and remove the primary tumor. It was done through an anterior approach by Dr. Allen, who found a very large tumor lying above and closely attached to the kidney. He did not attempt to discover whether it was in the kidney but removed the tumor and kidney together. The tumor was very adherent to the jejunum and was separated with a great deal of difficulty. When the tumor was finally removed and examined it was clear that it

that localization can hardly be other than suprasellar, primarily on the left side. We have less evidence as to the type of lesion. The commoner lesion would be a suprasellar tumor with repeated hemorrhages, but I cannot recall seeing in the literature or noting in our own cases repeated exacerbations of symptoms with pressure on neighboring structures, as must be the case here, in such tumors whereas that does occur frequently in aneurysm. So in spite of the fact that it is a rarer condition in this region I should put first aneurysm with fatal rupture—a fairly good-sized aneurysm,—with suprasellar tumor, secondly,—one which has bled repeatedly,—and thirdly, a tumor of the pituitary which has outgrown the confines of the sella and has become suprasella in location.

DR. TRACY B. MALLORY: Dr. White, you saw this patient. Have you anything to say?

DR. JAMES C. WHITE: Our first admission diagnosis was suprasellar cyst, and it was not until we had evidence of blood in the ventricle that we began to feel that it must be aneurysm. Perhaps if Dr. Ayer had not known about that he would not have made it his first choice.

DR. AYER: The hemorrhage into the ventricle would not disturb me, but finding a sac of blood is unlikely in tumor and is characteristic of aneurysm. I still may be wrong.

DR. WHITE: He had headaches, which could be attributed to arachnoid bleeding.

DR. AYER: No evidence for or against that.

DR. WHITE: The other evidence was that as he chopped trees and watched the stump he could not see the axe until it got there.

DR. WILLIAM B. BREED: Would the absence of calcification by x-ray make you more certain that it was not suprasellar cyst?

DR. AYER: A good many of these tumors do not have calcification. If we did find it, I think it would be against aneurysm.

DR. BREED: I just wondered how high a percentage does show calcification?

DR. AYER: I should have that information at my tongue's tip but I cannot recall. A number do that is all I can say.

CLINICAL DIAGNOSIS

Suprasellar cyst with hemorrhage

DR. AYER'S DIAGNOSES

- 1 Aneurysm, suprasellar
- 2 Tumor, suprasellar

ANATOMICAL DIAGNOSIS

Aneurysm of the left internal carotid artery

PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK: This was a ruptured aneurysm, a very unusual one, both because of its large size and its position. It was right above the sella and originated from the left internal carotid artery.

There is not much more to be said about it. There was blood in the ventricles, as well as in the subarachnoid space. The diagram shows where the aneurysm was situated.

oc — optic chiasm pc — posterior cerebral artery
A — aneurysm p — pons
lic — left internal carotid b — basilar artery
mc — middle cerebral artery

DR. MALLORY: There was a terminal subarachnoid hemorrhage.

DR. AUBREY O. HAMPTON: What was the condition of the sella turcica?

DR. KUBIK: There was slight erosion.

DR. AYER: It was shown by x-ray.

DR. HENRY R. VIETS: There is no evidence that it was syphilitic?

DR. AYER: The tests were all negative. Most of these intracranial aneurysms are not syphilitic.

left side. He was unconscious, and his eyes were closed. For the next five minutes the convulsions continued intermittently, and he licked his lips continuously. Finally the convulsions ceased, and he regained consciousness although his body remained stiff. The blood pressure was 120 systolic, 80 diastolic, after the convulsions. The right pupil was dilated and reacted only very slightly to light. He said that he felt dizzy and faint, and that the right side of his body was numb. The ankle jerk and arm reflexes were more active on the right, the knee jerks were both very active and equal, the right plantar reflex was equivocal, the left was normal, and there was sustained clonus on the right and unsustained clonus on the left. The following morning he was found lying face down on the floor breathing heavily with his mouth open. His eyes were partially open, staring straight ahead, and his face expressionless. His body was tense, and his arms were shaking. He was incontinent of urine and when spoken to answered incoherently. His pulse was very slow, strong and somewhat intermittent, and his blood pressure was 150 systolic, 70 diastolic. He could not state definitely how long the attack had lasted, and he remained restless and irrational for about an hour. Late that afternoon he suddenly got out of bed, seemed very dazed, and made aimless movements with his hands. He resisted attempts to put him to bed and then suddenly became comatose with gasping respirations. A left ventricular puncture was done as soon as possible, and the ventricle was found to be full of fluid blood. His condition improved somewhat after this, and an attempt was made to decompress the suprasellar region through a burr hole in the left temporal area. A cyst-like wall was punctured in the region of the sella, and about 6 cc of partially clotted blood was removed. Several hours later a second ventricular tap was done without much improvement, and he died shortly thereafter.

DIFFERENTIAL DIAGNOSIS

DR JAMES B AYER. For localization of the lesion the eye symptoms are obviously of greatest importance. The first symptom of illness was sudden transitory blindness, followed by progressive loss of vision first in the left, then in the right eye. This course strongly suggests a lesion at or near the only place where the visual pathways meet, that is, the optic chiasm, and this supposition is made more certain by the examination which discloses pallor of both optic disks and absence of light response in the left pupil. Whether due to pressure from above the chiasm or from below, or to a disorder of the optic pathways, is not certain at first, but shortly after the initial eye symptoms, numbness of the entire right side of

the body and falling to the ground suggest disturbance of sensory and motor pathways, cephalad to the pons on the left side, and absence of unconsciousness seems to exclude cortex as the seat of this attack. Numbness, weakness and increase in reflexes, found later, can best be explained by pressure upon the left crus cerebri. These two groups of symptoms, the visual and the sensorimotor, appear to place the lesion above and to the left side of the optic chiasm. The development of epilepsy later can well be explained on the basis of further extension of pressure to the uncus of the temporal lobe, a favorite origin for convulsions.

I see no evidence to point to direct labyrinthine or cerebellar dysfunction to explain vertigo on looking upward or slight unsteadiness.

What is the pathologic lesion? The evidence is in favor of a progressive expanding lesion, with several sudden attacks causing sudden loss of function in the territory mentioned. As blood was found in the lateral ventricle following one of these attacks, it is reasonable to think of aneurysm or a vascular neoplasm which bleeds periodically causing the acute symptoms mentioned in the history. Death seems to have been due to bleeding into the third ventricle.

The principal tumors to be considered as causing the above chain of events comprise two groups. First, there are those arising in the pituitary body itself and subsequently expanding through the diaphragm of the sella to cause pressure on neighboring structures. The preservation of the sella, although somewhat enlarged and the lack of outstanding endocrine symptoms (although some acromegaly is suggested by x-ray) render such tumors unlikely, although not excluded. Suprasellar tumors form the second group. Of these, the meningioma arising from the sella turcica or sphenoidal ridge must be considered, but probably excluded because its enlargement would be very slow and is not usually accompanied by violent access of symptoms. Tumors arising from cell rests in the pituitary stalk satisfy the given clinical course, they are frequently cystic and highly vascular.

Aneurysms in this neighborhood, arising from the anterior cerebral or anterior communicating arteries, single or bilateral, may cause progressive blindness, and by repeated bleeding produce transitory pressure upon neighboring structures. One would expect an aneurysm to rupture into the subarachnoid space, but there is no reason why it should not rupture into the third ventricle. The finding of a cyst-like wall containing blood clot suggests aneurysm although not excluding tumor.

Putting the evidence together it seems to me

social and health organizations, the establishment of welfare-department responsibility for medical care of the indigent and near-indigent, and the broadening of the functions of the local hospitals. It was further recommended that a State Health Council be established, which would act as a coordinating unit for the district councils and would serve as a deliberative body for consideration of the broader aspects of the problems. In the report of another subcommittee, the chairman, Dr Channing Frothingham, declared that "the indigent sick in any community could be cared for by the individual physician through the proper authorities. Plans for the fulfillment of this principle are now in operation in Franklin County and in various townships in other counties."

Although this report has been published in full in the Proceedings of the Massachusetts Medical Society, reference to it seems to be appropriate at this time, in order to stimulate more interest in the propositions set forth and thereby induce the district societies to put the recommendations in effective operation.

In this connection it is of interest to refer to the editorial in the *Journal of the American Medical Association* of January 15, where it is recorded that the Executive Committee of the Board of Trustees of the American Medical Association has adopted resolutions which cover practically all the important recommendations made by the subcommittee of the Massachusetts Medical Society and referred to above.

FUROR SCRIBENDI

It should be axiomatic that investigative work done in and published from teaching centers that are recognized as authoritative be both instructive and convincing. Unfortunately it requires only a superficial perusal of any medical journal to demonstrate that, in this respect at least, axioms are not what they used to be. "Competitive investigation," "furor scribendi," the adulation of the general public for the individual who screams loudest in print, and the commensurate increase in his earning capacity, all lead to bigger but poorer journals. This is especially anachronistic in medicine since hon-

esty of thought as well as accuracy of observation lies at the very foundations of this particular science. It is also true that the fault, if it be one, of publishing ill-considered and what might be called anemic papers lies equally with the editorial boards of these journals. Their action can be explained, and to some extent excused, by the fact that they still think that they provide what their readers want, especially as the latter have given no sign to the contrary.

A recent example of this sin against Aesculapius has been provided by a solemnly expounded thesis which deals with and draws conclusions from the study of less than twenty instances of an annoying physiologic condition that may affect slightly less than fifty per cent of the millions of people who form the population of the United States. Even the authority resident in the imprimatur from what is admittedly one of the leading institutions of this country cannot justify failure to use experimentally a few more, at least, of the possible millions before rushing into print. The observations made and conclusions drawn are unquestionably accurate. The reasons for publication, however, are—to put it mildly—inadequate, and as a matter of charity must be laughed at rather than condemned. However, it does not really matter! The paper can still be used to light a fire which will, after all, warm those who can but will not write, at the expense of those who will but should not.

THE MASSACHUSETTS PROBLEM OF ADEQUATE MEDICAL CARE

FORTUNATELY for the people of this country there are, in professional groups and among sociologists and philanthropists, men and women with vision and mental poise who are earnestly striving to relieve the misfortunes found among the victims of maladjusted social environment and of disease. Of these groups the physician is recognized as an important factor in bringing to bear remedial measures.

A great variety of plans have been formulated and experiments carried on designed to ameliorate the predicaments of those who seem to be unable to work out for themselves the solution of the problems involved. The medical profession has become conscious of its responsibility in co-operating with other agencies in dealing with disease and the associated economic factors, and has af-

firmed its readiness to give the quality and degree of service that is indicated.

With these objects in view, organized medicine in this State has, through the Massachusetts Medical Society, pledged its best efforts to meet the medical needs of all the people. This sentiment was made manifest through the creation of the Committee on Public Relations several years ago, which was composed of representatives of the eighteen district medical societies. In order to deal with problems connected with adequate medical care a subcommittee was appointed consisting of Dr. Ernest L. Hunt, chairman, and Dr. Halbert G. Stetson and Dr. Patrick J. Sullivan with instructions to study the economic conditions relating to adequate medical care for the people of Massachusetts.

In order to secure available information relating to the subject, a survey of 500 Massachusetts families comprising 1820 individuals, covering the economic burden incident to ill-health and many other associated matters, was carried on. Two years were devoted to this task, and a report of the committee's findings was given to the Council of the Massachusetts Medical Society, June 8, 1936, with recommendations which were approved. The survey disclosed the facts that untreated and imperfectly treated cases of illness existed in Massachusetts and that inadequate financial resources of patients accounted for a considerable proportion of the poor medical care, with other important contributing conditions set forth in the sixteen explanatory divisions. This study is being continued, and in a recent paper presented to the Worcester District Medical Society, Dr. Hunt declared that in at least thirty per cent of the cases of illness in Massachusetts there is some inadequacy of medical care.

The remedial measures designed to meet the conditions set forth in the report of this committee consist, first, in the creation of health councils in each district-society area, whose functions would include the education of the people as to the needs and possibilities of medical service and measures for securing it, the provision of suitable clinics, the obtaining of co-operation from industrial, fraternal

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 14

BARNSTABLE

Sunday, March 20, at 4 00 p m., at the Cape Cod Hospital, Hyannis. Subject. Gonorrhea in the Male. Instructor Roger C. Graves John I B Vail, *Chairman*

BERKSHIRE

Thursday, March 17, at 4 30 p m., at the House of Mercy Hospital, Pittsfield. Subject Some Complications of Labor Analgesics in Labor Instructor Christopher J Duncan Melvin H Walker, Jr., *Chairman*

BRISTOL SOUTH (Fall River Section)

Monday, March 14, at 4 30 p m., at the Union Hospital, Fall River Subject Bleeding in the First Trimester of Pregnancy Instructor M. V Kappius. Howard P Sawyer and Robert H Goodwin, *Chairmen*

ESSEX NORTH

Friday, March 18, at 4 00 p m., at the Lawrence General Hospital, Lawrence. Subject Bleeding in the First Trimester of Pregnancy Instructor Judson A. Smith. John Parr, *Chairman*

FRANKLIN

Wednesday, March 16, at 8 00 p m., at the Franklin County Hospital, Greenfield. Subject The Use and Misuse of Prontylin. Instructor Benjamin W Carey, Jr Halbert G Stetson, *Chairman*

HAMPDEN

Thursday, March 17, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor Sylvester McGinn. George D Henderson and George L. Schadt, *Chairmen*

HAMPSHIRE

Wednesday, March 16, at 4 15 p m., in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject Gonorrhea in the Male. Instructor Oscar F Cox, Jr Warren P Cordes, *Chairman*

MIDDLESEX EAST

Tuesday, March 15, at 4 00 p m., at the Melrose Hospital, Melrose. Subject Acute Anterior Poliomyelitis—Its Diagnosis and Treatment. Instructor R. Cannon Eley Joseph H. Fay, *Chairman*

MIDDLESEX SOUTH

Wednesday, March 16, at 4 00 p m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject Atelectasis in the Newborn. Instructor Clement A. Smith. Edmund H Robbins, *Chairman*

NORFOLK

Friday, March 18, at 8 30 p m., at the Norwood Hospital, Norwood. Subject The Use of Vitamins in Pediatric Practice. Instructor Louis K. Diamond Hugo B C. Riemer, *Chairman*

PLYMOUTH

Tuesday, March 15, at 4 00 p m., in the Rosa Field Nurses Residence, Brockton Hospital (rear of hospital), Brockton Subject Differential Diagnosis and Treatment of Scarlet Fever Instructor Charles F McKhann, Jr Walter H. Pulsifer, *Chairman*

DEATH

GUGENBERGER — JOSEPH GUGENBERGER, M.D., of 460 Park Avenue, Worcester, died February 28, 1938 He was in his forty fifth year

He was a native of Alsace Lorraine, but came here when very young He received his early education in Holvoke and later went to the Worcester City Hospital to study nursing At the outbreak of the World War he postponed his training to serve as a sergeant in the Medical Corps at Fort McHenry, Baltimore, Md. After the Armistice he returned to the Worcester City Hospital and finished his training, graduating in 1920

For four years he practiced as a graduate nurse in New York City and then began premedical training at Columbia University In 1928 he enrolled at the Long Island College of Medicine, received his degree in 1932, and served his internship at the Worcester City Hospital Three years ago he established a practice at his home.

Dr Gugenberger was a member of the American Medical Association and a fellow of the Massachusetts Medical Society

His widow, two brothers, and two sisters survive him.

MISCELLANY

ANNOUNCEMENT OF THE FRANCIS AMORY SEPTENNIAL PRIZE OF THE AMERICAN ACADEMY OF ARTS AND SCIENCES UNDER THE WILL OF FRANCIS AMORY

In compliance with the requirements of a gift under the will of the late Francis Amory of Beverly, Massachusetts, the American Academy of Arts and Sciences announces the offer of a septennial prize for outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs, to be known as the Francis Amory Septennial Prize. The gift provides a fund, the income of which may be awarded for conspicuously meritorious contributions to the field of knowledge "during the said septennial period next preceding any award thereof, through experiment, study or otherwise in the diseases of the human sexual generative organs in general. The prize may be awarded to any individual or individuals for work of "extraordinary or exceptional merit" in this field.

In case there is work of a quality to warrant it, the first award will be made in 1940 The total amount of the award will exceed ten thousand dollars, and may be given in one or more awards. It rests solely within the discretion of the Academy whether an award shall be made at the end of any given seven-year period, and also whether on any occasion the prize shall be awarded to more than a single individual.

tient had felt no fetal motions for twenty-four hours

The family history was unimportant, and her past history was essentially negative. There had been thirteen full-term pregnancies and one early miscarriage. In 1912 a pelvic abscess developed after one delivery and this was drained.

The patient was not followed in the prenatal clinic and so far as was known had had no prenatal care at all. Physical examination on admission showed a woman who had evidently lost a good deal of blood. The mucous membranes were pale. The lungs were normal, and there were no rales. The heart showed no murmurs or enlargement. The sounds were very weak, with regular rhythm and a rate of 64 per minute. The blood pressure was 50 systolic, 30 diastolic. The abdomen showed a full-term uterus in constant contraction. No fetal heart sounds were heard, and no fetal motions were felt. Rectal examination revealed that the head was in the pelvis, and the cervix dilated to admit two fingers. She was still bleeding.

The patient was at once given 500 cc of 10 per cent glucose with 15 units of insulin, intravenously, morphine and sodium amytal were given to control the patient's restlessness. Her blood was taken for typing, and a compatible donor secured. A Spanish windlass was applied to the abdomen and pressure made on the uterus. The patient was also given Thymophysin to stimulate uterine contraction and hasten delivery. During this time the blood pressure remained very low, the pulse rate was 64 per minute but the volume small. The patient was in severe shock. At 1 p. m., 1000 cc of saline solution was administered under the breasts, 500 cc of citrated blood was transfused at 4 p. m., at which time the patient's pulse was becoming weaker. Hot water bottles and blankets were applied and restoratives given. The patient had been bleeding since admission, and by 6 p. m. it was quite evident that she was steadily losing ground. After consultation among the staff it was decided that the patient's only hope was immediate delivery. Under nitrous oxide the membranes were ruptured, dilatation of the cervix was completed, and a dead baby delivered by internal podalic version, the baby weighed 5 lb, 9 oz. The uterus did not contract well, and the patient continued to bleed, hence, the uterus was firmly packed. As the patient was in very poor condition, she was given oxygen and carbon dioxide, intravenous glucose and injections of caffeine and sodium benzoate, but her condition grew steadily worse, and she died at 7.55 p. m.

At autopsy, approximately 200 cc of thin fluid blood was found on opening the abdominal cav-

ity. The important features of the examination are given in the following extracts: "The serosa of the jejunum and ileum show occasional dark red areas completely encircling the wall for a distance of about 7 cm. Otherwise the serosa is negative. The stomach contains approximately 2 liters of thin bright-red blood. The duodenum, jejunum and upper end of the ileum contain similar bright-red blood. Upon washing this away, the mucosa lining the stomach, duodenum and jejunum is markedly injected, the capillaries being very prominent and strongly suggesting a possible source of oozing. This capillary engorgement is most marked beneath the regions of redness in the serosa, above noted. No frank rupture of vessels can be found. The esophagus shows no evidence of varices. At no point in the gastrointestinal tract is there any evidence of cancer."—"The uterus is massively distended and thinned, extending upward halfway to the umbilicus. Its serosa is smooth and glistening. Beneath it are extensive extravasations of blood. At no point is the uterine wall more than 1 cm in thickness. It is completely packed with blood soaked gauze. The endometrium is reddened and, over the recent site of placental attachment, is completely raw. The cervix is widely dilated, easily admitting one's fist."

The following are extracts from the microscopic examination: "*Ileum*. The wall, per se, is negative. The capillaries of the villous processes are enormously distended and in many places frankly ruptured."—"Uterus. The musculature is thinned, shows generalized degeneration and is markedly edematous and in places hemorrhagic. The endometrial surface shows no evidence of infection."

Comment. It must be remembered that this case was treated in 1932. Like treatment today would be open to a good deal of criticism. Transfusion should not have been delayed twelve hours, the patient should have been transfused as soon as she entered the hospital. It is fair to state that a woman who had had thirteen children and who had a baby that weighed only 5 lb, 9 oz, would have been delivered normally long before 6 p. m. had the present-day method of rupturing the membranes as soon as she reached the hospital and applying a Spanish windlass been instituted. The internal podalic version followed by immediate extraction of the child through a cervix that was not dilated possibly added to the shock. Although there is no urinalysis reported, it is quite probable that this woman was suffering from a toxic separation of the placenta and that the blood in her stomach resulted therefrom. While the pathological findings in the jejunum and ileum are not pathognomonic of toxic separation, they are quite compatible.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JANUARY, 1938

DISEASES	JANUARY 1938	JANUARY 1937	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	1	1
Chickenpox	2196	1772	1786
Diphtheria	17	20	63
Dog bite	640	580	451
German measles	57	76	241
Gonorrhea	376	519	505
Lobar pneumonia	532	843	835
Measles	566	4024	2714
Meningococcus meningitis	3	13	10
Mumps	618	719	905
Paratyphoid B	1	0	0
Scarlet fever	1163	991	1150
Syphilis	433	510	425
Tuberculosis pulmonary	270	295	292
Tuberculosis other forms	38	26	33
Typhoid fever	7	3	6
Undulant fever	2	5	2
Whooping cough	599	2167	1172

*Based on figures for preceding five years

RARE DISEASES

Diphtheria was reported from Athol, 1, Boston, 7, Chelmsford, 1, Fall River, 1, Haverhill, 1, New Bedford, 1, Revere, 1, Taunton, 3, Woburn, 1, total, 17

Dysentery, bacillary, was reported from Danvers, 4, New Bedford, 1, Somerville, 1, total, 6

Malaria was reported from Newton, 1

Meningococcus meningitis was reported from Boston, 2, North Reading, 1, total, 3

Paratyphoid B was reported from Greenfield, 1

Pfeiffer bacillus meningitis was reported from Norfolk, 1

Septic sore throat was reported from Athol, 1, Boston, 10, Gardner, 5, Medford, 1, Northfield, 2, Quincy, 1, Salem, 2, Somerville, 1, Springfield, 1, Sturbridge, 2, total, 26

Trichinosis was reported from Brookline, 1, Medford, 1, Quincy, 1, total, 3

Typhoid fever was reported from Boston, 1, New Bedford, 1, Quincy, 1, Somerville, 1, Springfield, 1, Worcester, 2, total, 7

Undulant fever was reported from North Adams, 1, Quincy, 1, total, 2

Diphtheria showed a record low incidence.

The incidences of scarlet fever and tuberculosis (other forms) were reported above the five year average.

Pulmonary tuberculosis had record low figures with the exception of January, 1933, which showed an equally low incidence.

Lobar pneumonia, whooping cough and measles were reported at figures considerably below the five year average.

The incidence of undulant fever was not remarkable.

Meningococcus meningitis was reported at a record low figure.

Chickenpox showed record high incidence both for this and any other month to date.

The incidences of mumps and German measles were below the five year average.

Anterior poliomyelitis showed record low incidence.

The incidence of animal rabies was not remarkable.

New foci were reported in Brockton and Dunstable. Previously noted foci in Lowell and the North Shore were active.

STUDY OF NURSING FOR THE TUBERCULOUS

The lack of standards for nursing in tuberculosis sanatoriums has been so much complained about to people with whom national nursing organizations and the National Tuberculosis Association correspond that a study is proposed

Its first object is to determine what constitutes adequate nursing care of tuberculosis patients. Secondly, it is proposed to gather information that will provide an index of the amount of time needed to give that care. The project will be under the direction of the Department of Studies of the National League of Nursing Education.

Dr Sumner H. Remick, superintendent and medical director of the Middlesex County Sanatorium at Waltham, has been advised by Dr Kendall Emerson, managing director of the National Tuberculosis Association, and Miss Mary A. Hickey, R.N., chairman of the Joint Committee for the Study of Tuberculosis Nursing, that the Middlesex County Sanatorium has been selected as one of the limited number of institutions where the study will be made.

Dr Remick has replied favorably indicating that he hopes that the study will be of service not only to his but to other tuberculosis sanatoriums

VOCATIONAL SERVICE BUREAU OF THE AMERICAN PHYSIOTHERAPY ASSOCIATION

Trained physiotherapists are always available through the Vocational Service Bureau of the American Physiotherapy Association. This association was organized very soon after the close of the World War, the charter members being former reconstruction aides-in-service. Since then the membership has increased to more than 800. The present requirements for membership are an approved course in physical therapy of not less than nine months, following graduation from a school of nursing or physical education which meets with the requirements of the individual states and one year's practice in physical therapy within two years of graduation from an approved school of physical therapy. These requirements have been approved by the Council on Medical Education and Hospitals of the American Medical Association. The object in having these qualifications for membership is to provide, for the hospitals, schools for crippled children and offices of physicians, trained physiotherapists who are able to follow physicians' orders intelligently and thoroughly.

Those desiring such service should communicate with Miss Edith Munro, 483 Beacon Street, Boston (Ken 8000)

CORRESPONDENCE

PATHOLOGICAL TECHNIC

To the Editor While heartily agreeing with the reviewer in his praise of Dr Sidney Farber's valuable book *The Postmortem Examination* I feel that I must take exception to one statement by the reviewer "There are minor faults, such as the indication that removal of the organs of the neck is a standard and usual procedure in autopsy technic. I can hardly believe that the reviewer meant to imply that routine examination of the organs of the neck is not standard and usual. I believe that what he did mean to imply was that removal of all

the organs of the neck, including trachea, larynx and tongue, is not a usual procedure at least in adults.

Any pathologist who regards an autopsy complete without careful examination of the thyroid, cervical lymph nodes and parathyroids, together with inspection in situ of the trachea and larynx, can hardly be said to be performing a standard autopsy

REPORT OF MEETING

THE WILLIAM HARVEY SOCIETY

A meeting of the William Harvey Society was held on January 14 at the Beth Israel Hospital. Dr James J. Hepburn presided and after a brief historical review of thoracic surgery introduced the speaker of the evening Dr Edward D. Churchill who spoke on "Thoracic Surgery."

In opening his talk he pointed out that progress in surgery of the chest had lagged behind that of other branches of surgery until the last 10 or 15 years because thoracic surgery depends on an accurate knowledge not only of anatomy, pathology and principles of asepsis, but also of the principles of cardiorespiratory physiology. The rapid development of the x ray, the use of radio-opaque oil in injections and the use of the bronchoscope are other important factors in the development of this prominent branch of surgery

Empyema is the most frequent of the surgical diseases of the chest which is seen by the general practitioner and which requires speedy treatment. The principles used in the treatment of empyema are first, drainage of the pus by a method suited to the patient so that there will be no further crippling of the cardiorespiratory functions, secondly, a restoration of the function of the lung, and thirdly, the obliteration of the infected cavity. The general practitioner must make an early diagnosis and should use an aspirating needle if there is doubt. It is important to know when to remove the drainage tube, as much damage can be done by leaving the tube in too long. Chronic empyema is a distressing condition which usually results from improper treatment. Lantern slides of a case of chronic empyema were shown. These cases require very extensive surgery.

The field of tuberculosis has only recently been invaded by thoracic surgeons. The first operation of this sort that was done in Boston occurred in 1920. The fundamental principle upon which this type of therapy is based is putting the diseased lung at rest and repairing the damage by collapsing the cavities. Pneumothorax is used wherever possible and is effective when a good collapse can be obtained. In certain cases adhesions will prevent this method from giving collapse, and in many of these cases the adhesions can be severed. The phrenic nerve at times is crushed to help put the lung at rest. Thoracoplasty is used where other means are not effective, the ribs being resected over the pleura. The progress in this operation has been rapid in the last decade, and at the present time a good collapse can be obtained without deforming the patient excessively. Dr Churchill spoke briefly on tuberculous empyema and pointed out the importance of always demonstrating pyogenic organisms before draining any empyema because if it is tuberculous it should not be drained.

In the treatment of patients with lung abscesses the careful combination of medical and surgical care is necessary. In certain cases drainage is done, but a needle should never be introduced because of the danger of causing pyopneumothorax. Dr Churchill warned against tonsillectomies being done in the home, particularly under general anesthesia, because of the danger of postoperative lung abscess. In certain cases it is necessary to remove a whole lobe of the lung in order to get rid of the abscess.

In the treatment of bronchiectasis it is found that simple drainage or collapse is not effective. The involved lobe must be removed. The mortality in these cases at the Massachusetts General Hospital since 1930 has been 44 per cent. Usually the patients are debilitated at the time operation is contemplated.

Primary carcinoma of the lung seems to be on the increase. It is absolutely necessary to have early x rays and determine the cause of chest symptoms, because the surgical treatment of this condition depends entirely on the early diagnosis. One lobe, two, or an entire lung may be removed for this condition. Total pneumonectomy is still a dangerous operation. Operation in these cases is feasible in about 30 per cent. In the 18 cases done at the Massachusetts General Hospital, 6 are living, 5 are dead of metastases and 7 died following operation. Benign tumors usually cannot be differentiated from carcinoma. Hemoptysis is often an early symptom in these cases. Examples of this type of tumor are dermoid cysts, echinococcus cysts, thyroid adenomas and neurofibromas.

Tumors of the ribs which occur near the chondral junction are frequently slow growing chondrosarcomas and the entire rib should be removed. Dr Churchill closed by stating that there were many other problems of

chest surgery, including surgery of the esophagus, diaphragmatic hernias and the removal of adenomatous goiters. He feels that great progress will be made in the future.

NOTICES

REMOVALS

ARAM KAVALGIAN, M.D., announces the removal of his office to 435 Mt. Auburn Street, Watertown

JAMES B. HICKS, M.D., announces the removal of his office to 1101 Beacon Street, Brookline.

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve-thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen discussed, and when indicated, treated with radium and high-voltage x ray.

Physicians are welcome to visit this clinic and bring a patient to the clinic for diagnosis

THOMAS WILLIAM SALMON MEMORIAL LECTURES

The Salmon Committee on Psychiatry and Mental Hygiene invites the medical profession and its friends to The Sixth Series of Thomas William Salmon Memorial Lectures

This series will be given by Dr. David Kennedy Henderson, physician superintendent of the Royal Edinburgh Hospital for Mental Disorders, Scotland, April 18, 19 and 20, at the New York Academy of Medicine, 2 East 103rd Street, at 8 30 p. m.

Dr. Henderson will speak on "Psychopathic States" according to the following schedule

April 18 Their Place in Psychiatry

April 19 Their Characteristics as Evidenced by Aggression, Inadequacy and Creativeness

April 20 Their Understanding and Synthesis.

Dr. Henderson is professor of psychiatry at the University of Edinburgh and is well known as a consultant and lecturer. He was a major in the World War and the author of several papers on the war psychoses. He holds the degrees of F.R.C.P. (Edinburgh) and F.R.F.P.&S (Glasgow) and is the author of more than thirty publications on psychiatric subjects

THE SIR WILLIAM OSLER SOCIETY

The annual lecture of the Sir William Osler Society of Tufts College Medical School will be given on Friday evening, March 18, in the auditorium of the Beth Israel Hospital, at 8 00. Dr. Henry A. Christian will speak on "The Fruition of the Clinician."

STANLEY STELLAR, *Secretary*

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The next regular meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, March 16, at 8 o'clock. The council will meet at 6 00, and informal dinner will be served at 6 30 in the Empire Room.

Dr. Heinrich Brugsch and Dr. Joseph H. Pratt will speak on "The Indications and Contraindications of Ultra Short Wave Therapy based on observations of cases

treated at the Boston Dispensary. Discussion Dr. William D. McFee

All members of the medical profession are cordially invited to attend.

WILLIAM D. McFEE, M.D., *Secretary*

THE GEORGE W. GAY LECTURE ON MEDICAL ETHICS

The George W. Gay Lecture on Medical Ethics "A Few of the Rules" will be given by Dr. Reginald Fitz, in amphitheater E of the Harvard Medical School, on Tuesday, March 15, at 5 00 p. m.

MASSACHUSETTS MEMORIAL HOSPITALS

There will be a luncheon meeting of the surgical section in the Aid Association Room, Talbot Memorial Building, 82 East Concord Street, Boston, on Friday, March 11, at 12 o'clock noon.

MILO C. GREEN, M.D., *Secretary*

CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital, 330 Mt. Auburn Street, Cambridge, on Tuesday, March 15, at 8 30 p. m.

All members of the medical profession are cordially invited to attend.

JOSEPH M. WADDEN, M.D., *Secretary*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), Tuesday, March 22, at 8 15 p. m.

PROGRAM

Presentation of Cases

The Pigments and Color of Living Human Skin. Dr. E. A. Edwards and Dr. S. Q. Duntley

Medical students and physicians are cordially invited to attend

MARSHALL N. FULTON, M.D., *Secretary*

BOSTON SOCIETY OF ANESTHETISTS

The next regular meeting of the Boston Society of Anesthetists will be held at the Hotel Kenmore, on Tuesday, March 15, at 7 45 p. m.

Dr. G. Philip Grabfield will speak on "Clinical Thoughts on Pharmacology of Central Nervous-System Depressants"

LEO V. HAND, M.D., *Secretary*

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

The next meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library, on Thursday evening, March 17, at 8 15

PROGRAM

The Pathogenesis of Syphilitic Optic Atrophy. Dr. Samuel H. Epstein

Psychoanalytic Observations on Two Cases with Preconvulsive Aurae. Dr. Ives Hendrick

Electrical Signs of Corneal Lesions. Dr. Denis Williams

H. HOUSTON MERRITT, M.D., *Secretary*

TUFTS MEDICAL ALUMNI CLUB OF WORCESTER COUNTY

There will be a meeting of the Tufts Medical Alumni Club of Worcester County on Wednesday evening, March 16, at the Bancroft Hotel. Dinner will be served at 6.30, the business meeting will be held at 7.30

Dr Abraham Myerson will speak on Human Autonomic Pharmacology'

C J BYRNE, M.D., *President*
N S SCARCELLO, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MARCH 14

TUESDAY MARCH 15

- *9-10 a. m. Boston Dispensary Clinicopathological Conference. Dr R. C. Wadsworth.
- 10 a. m. 12.30 p. m. Tumor clinic. Boston Dispensary
- *12 m. South End Medical Club. Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue, Boston
- 7.45 p. m. Boston Society of Anesthetists. Hotel Kenmore Boston
- 5 p. m. George W. Gay Lecture on Medical Ethics. Amphitheater E of the Harvard Medical School.

WEDNESDAY MARCH 16

- *9-10 a. m. Boston Dispensary Hospital case presentation. Dr S J Thannhauser
- 8 p. m. New England Society of Physical Medicine. Hotel Kenmore, Boston
- *12 m. Clinicopathological conference. Children's Hospital Amphitheater

THURSDAY MARCH 17

- 8.30-9.30 a. m. Exchange visit, surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals, held this week at the Children's Hospital
- *9-10 a. m. Boston Dispensary Allergic Manifestations in Certain Dermatoses. Their Recognition and Treatment. Dr Francis M. Thurston.
- 8.15 p. m. Boston Society of Psychiatry and Neurology Boston Medical Library 8 Fenway

FRIDAY MARCH 18

- *9-10 a. m. Boston Dispensary Certain Clinical Features of the Natural History of Rheumatic Fever and Heart Disease. Dr T. Duckett Jones.
- *10 a. m. 12.30 p. m. Tumor clinic Boston Dispensary
- 12 m. Clinical meeting of the Children's Medical Service, Massachusetts General Hospital, Ether Dome.
- 8 p. m. Sir William Osler Society Auditorium Beth Israel Hospital Boston

SATURDAY MARCH 19

- *9-10 a. m. Boston Dispensary Hospital case presentation. Dr S. J. Thannhauser
- *10 a. m. 12 m. Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian

SUNDAY MARCH 20

- 4 p. m. Illustrated public health lecture, Faulkner Hospital auditorium. Diseases of the Prostate Gland (men only) Dr Franklin Balch, Jr
- 4 p. m. Free public lecture. Harvard Medical School amphitheater of Building D. The Family Medicine Cabinet. Home Remedies and When to Use Them Dr Reginald Fitz.

Open to the medical profession.

BOOK REVIEWS

Quelques Verites Premieres (Ou Soi Disant Telles) sur Les Maladies Infectieuses A. Lemierre. 76 pp Paris Masson et Cie, 1937 24 Fr fr

This little book is one of a series of nine volumes which are being sponsored by Ombredanne and Fiessinger. The purpose of these books is to have different clinicians who have specialized knowledge of a subject make a se

ries of general statements concerning different diseases. The present volume contains 'verités premières' about infectious diseases and covers the different types of fever, the septicemias, the exanthems, grippe, erysipelas and angina, with remarks on prophylaxis and therapeutics.

Professor Lemierre has listed the various points as aphorisms and most of the statements are well recognized facts to all physicians and students of infectious diseases. There are a number of statements which are noteworthy and anyone interested in infectious disorders will find this book of value.

Les Acquisitions Nouvelles de l'Endocrinologie R. Rivoire.
Third edition 264 pp Paris Masson & Cie, 1937
45 Fr fr

This, the third edition of the author's monograph on recent advances in endocrinology, is an exceptionally good survey, for the student or practitioner, of the status of this subject. For the investigator or one about to write upon the subject the book is utterly useless as there is not a single reference to the literature in the whole volume. This glaring fault reduces the value of the book by at least fifty per cent, in spite of the fact that the author has obviously covered the literature very thoroughly, not only in his own language but also in English. The author's views in his preface to this edition strike the keynote to the whole book, he says that "as one will see on reading the book, the hypothetical side has been greatly cut down and it is for the author a great satisfaction to have seen, little by little, physiological, biochemical and clinical researches confirm in great part the theories which he propounded since the beginning of the new era in endocrinology."

Synopsis of Gynecology Harry Sturgeon Crossen and Robert James Crossen. Second edition 247 pp
St. Louis The C V Mosby Company, 1937 \$3 00

This *Synopsis of Gynecology* is based on Crossen's *Text-book of Diseases of Women*, one of the well known standard works. There are twenty chapters, over one hundred illustrations and a good index, in a volume which is compact, handy, and if one knows how to use a synopsis, useful. In general it is well written, and the synoptic presentation is well made and comprehensive.

But this reviewer suggests that a picture of the ovum accompany the description on page 16, that on page 69 respiratory excursion of the abdominal wall be noted, that the resources of abdominal auscultation be not overlooked. The press work is satisfactory, but the type for headings is confusing, as there is lack of uniformity in using larger type for more comprehensive headings.

Bright's Disease and Arterial Hypertension Willard J Stone. 352 pp Philadelphia and London W B Saunders Company, 1936 \$5 00

This is a very well written and extremely well illustrated summary of what is generally known concerning the facts and theories of Bright's disease. The initial chapter reviewing historical sequences is of more than passing interest. The succeeding chapters in the first half of the book deal with classification of the disease and a discussion of the various chemical phenomena associated with the diagnosis and study of Bright's disease and its complications. This section of the book is very clearly written, but does contain a certain amount of repetition, especially concerning methods of study which are not in general clinical use. A summary of the methods found clinically useful would be helpful.

The second portion of the book deals with a discussion of the specific forms of Bright's disease, with their diagnosis and treatment, and finally, there is a rather brief discussion of hypertension in its relation to kidney disease. At times the reviewer is somewhat confused over the various clinical subdivisions of the disease and feels that perhaps the matter of classification is a little over emphasized. On the other hand, the consideration of the problem of hypertension is perhaps somewhat inadequate.

In general, the book presents nothing new, but it does present a good, sound summary of what is known about Bright's disease, its diagnosis and treatment.

Rose and Carless Manual of Surgery Edited by William T Coughlin American (fifteenth) edition. 1586 pp
Baltimore William Wood & Company, 1937 \$9 00

When a work in a period of forty years has reached fifteen English editions and as many reprints, a number of American editions, and translations in Arabic, Chinese and Hungarian, one is curious to learn the cause of its popularity. The fact that the work covers a very wide field of surgery and is contained in a single volume may appeal to many practitioners and students. As the volume contains about 1600 pages it is necessarily bulky, but its strong binding and calendered paper greatly facilitate its use. The text is clear and concise. The topical arrangement and the employment of heavy faced type for subheadings make it easily readable. Over 900 well selected and well-captioned illustrations and an excellent 50-page, double-column index greatly enhance its value as a reference book.

The preface to the English edition states that new chapters on 'Surgical Shock' and 'Surgery of the Sympathetic Nervous System' have been added and that the chapters on 'Thoracic Surgery,' 'Surgery of the Central Nervous System,' and 'Anesthesia' have been extensively rewritten. The text under examination is edited by William T Coughlin from the fifteenth English edition by Wakeley and Hunter. Some parts of the sections relating to the specialties have been omitted. Chapters on the ear, nose, throat, and genitourinary diseases are retained and comprise 125 pages. The chapters on gynecology and tropical surgery have been omitted from the text. References to them have not been deleted from the index, but at the beginning of the index is a statement that "all entries after page 1536 referred to the British edition only."

The work has a British flavor both in phraseology and terminology. Considering its wide scope it is a splendid practical book. A conspicuous feature is the clear description of gross and microscopic anatomy.

Variations in methods of treatment from some of our own are to be expected and are frequently stimulating. There are, however, certain commissions and omissions which seem of sufficient importance to the reviewer to be noted—the sections on fractures of the neck of the femur and pathologic fractures seem inadequate, there is no mention of the Nather Ochsner operation for subphrenic abscess (page 1145), the tendon suture described is not ideal for hand surgery (page 468), no external part of the sac of a spina bifida should be infolded (page 809), the benefit from Coley toxins cannot be judged in a few days (page 221).

It is a splendid single volume surgery for the student and practitioner, and its up-to-dateness in certain portions is pleasantly surprising in a work of this scope.

NUMBER 11

THE DIAGNOSIS, TREATMENT AND END RESULTS IN GONOCOCCAL ARTHRITIS

A Study of Seventy Cases

WESLEY W SPINK, M.D.,* AND CHESTER S KEEFER, M.D.†

BOSTON

GONOCOCCAL arthritis is one of the commonest and most severe complications of a gonococcal infection. Successful treatment depends upon a correct early diagnosis and a course of therapy definitely planned to prevent chronicity and disability. During the past three years we have carried out studies on 70 patients with proved gonococcal arthritis. The present report includes a discussion of the aids in making the correct diagnosis, the therapy utilized and the end results.†

DIAGNOSIS

The criteria for the correct diagnosis of gonococcal arthritis are as follows: (1) a history of a local gonococcal infection, either immediately preceding the attack of arthritis or at some time in the past, (2) smears and cultures of urethral or cervical exudates which reveal the presence of gonococci, (3) positive gonococcal complement-fixation tests of either the blood serum or the synovial fluid, and (4) the presence of gonococci in the aspirated contents of the joints or tendon sheaths.

A past history of gonorrhea in a patient with an acute onset of arthritis is not sufficient evidence for a diagnosis of gonococcal arthritis. If in addition to the history, examination of the blood serum or synovial fluid reveals a positive gonococcal complement-fixation test, we have reason to believe that the patient has gonococcal arthritis. In this connection, we have encountered male patients with an acute arthritis who presented a history of gonorrhea many years previously. There was no evidence of a recurrence of the local in-

fection, and complement-fixation tests of the blood were negative. However, bacteriological examination of synovial fluid aspirated from the joints revealed gonococci in pure culture. Likewise, a group of female patients with acute polyarthritis presented no history of a localized gonococcal infection. The diagnosis of gonococcal arthritis was made only after positive gonococcal complement-fixation tests had been obtained from the blood serum, or gonococci had been isolated from cervical exudates and synovial fluids, or both. The problem of latent gonorrhea as a cause of acute polyarthritis has been discussed in detail elsewhere.¹

In every case where gonococcal arthritis is suspected, one should carefully examine stained smears of prostatic or cervical secretions. Although the finding of gram-negative intracellular diplococci in these smears may be considered sufficient evidence for the diagnosis of gonorrhea, in most instances we have also cultured the secretions. This is particularly necessary in women where the presence of many different organisms may be confusing. Instances have occurred in which gonococci were not demonstrated in smears but culture of the exudates revealed their presence. In every case where the organisms have been isolated in pure culture we have proved them to be gonococci by agglutination and fermentation tests. Growth of the gonococcus is fostered best in an atmosphere with an increased carbon-dioxide tension, and the candle jar, as described by Nye and Lamb,² is utilized for this purpose. The method of culturing such exudates is as follows: Material is obtained from the cervix or urethra with a sterile swab. This is then placed in a tube of veal-infusion broth. A few drops of the broth are then smeared on 15 per cent horse-blood-agar plates. The plates are incubated at 37.5°C in the candle jar for from thirty-six to forty-eight hours. At

*From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital and the Department of Medicine, Harvard Medical School, Boston.

†We are indebted to Dr. Otto Hermann and his associates on the Orthopedic Service of the Boston City Hospital for the surgical care of these patients.

Formerly resident physician, Thorndike Memorial Laboratory, Boston City Hospital. Now assistant professor of medicine, University of Minnesota Medical School.

Associate professor of medicine, Harvard Medical School. Associate physician, Thorndike Memorial Laboratory, Boston City Hospital.

the end of this time colonies of the gonococcus appear glistening, elevated and slightly opaque

As has been indicated above, the gonococcal complement-fixation test is of considerable value in the diagnosis of gonococcal arthritis. This test can be done on either blood serum or synovial fluid. In several patients in our series the first definite evidence that they had gonococcal arthritis was based on a positive gonococcal complement-fixation test. Myers and Keefer³ have discussed in detail the results of this test, and more recently Warren, Hinton and Bauer⁴ have advocated its more general use. The results of the gonococcal complement-fixation test of the blood and synovial fluid in the present series of cases are tabulated in Table 1.*

Table 1 *Results of Gonococcal Complement-Fixation Tests on Synovial Fluids and Blood Serums of Patients with Gonococcal Arthritis*

Synovial fluids	
Sterile fluids	
Positive	16
Negative	7
Doubtful	1
Infected fluids (gonococci)	
Positive	5
Negative	6
Blood serums	
Positive	47
Negative	5
Doubtful	2

The higher incidence of positive reactions on the blood is due to repeated tests' being done on the blood, whereas a comparable number of determinations could not be carried out on synovial fluid. Six of the eleven samples of synovial fluid with gonococci present gave negative fixation reactions. As we have explained elsewhere,⁵ this absence of antibodies accounts in part for the finding of the gonococci. We have found positive reactions as early as the first week of the disease, and some patients have continued to have positive tests from two to three years after all symptoms have subsided.

The aspiration and study of synovial fluid from patients with arthritis are of value in the differential diagnosis. The routine procedure after obtaining the fluid includes a total-cell count, gonococcal complement-fixation test, Wassermann test and culture. Myers, Keefer and Holmes⁶ have described the characteristics of the synovial fluid in gonococcal arthritis. They were able to divide such fluids into two groups, on the basis of the presence or absence of organisms. The average cell count was higher in the infected fluids which had a preponderance of polymorphonuclear leukocytes. In both types of fluid the total protein content was above normal, the nonprotein nitrogen value was the same as that of the blood, and the sugar content varied according

to the presence or absence of organisms, the number of leukocytes and the blood-sugar level. In our series the total cell count of the sterile fluids was usually below 25,000 per cubic millimeter. In 17 (24 per cent) of the cases we were able to isolate gonococci from the synovial fluid, and they were isolated from material obtained from a tendon sheath in 4 patients.

TREATMENT

In order to clarify the end results of treatment, the patients have been divided into three groups. Group I comprised 26 patients who were treated by medical means alone. In Group II, 24 patients had sufficient evidence of an effusion into one or more joint spaces to warrant aspiration of the synovial fluid in addition to medical therapy. Group III was composed of 20 patients whose joints were aspirated and also opened and followed by lavage.

The medical treatment of all these patients had for its objectives the maintenance of the patient's general nutrition, the prevention of pain and deformities, the restoration of full function of diseased joints through physiotherapy, and the control of the local genitourinary tract infection. The patients were given a diet sufficient in caloric content and supplemented with accessory food-derived substances. Some of them developed a severe hypochromic anemia during the course of their illness, which was corrected by administering ferrous sulfate, except in two cases where whole-blood transfusions were given. Joint pains were relieved by immobilization and by medication in the form of salicylates and opiates.

During the acute stage of the arthritis, few attempts were made to treat the local genitourinary infection, aside from vaginal douches. On several occasions when fever and joint pains had subsided, massage of the prostate gland was done. It was not unusual for patients to have a flare up of their polyarthritis with fever following this maneuver.

Vaccines were administered intravenously to 11 patients. The vaccines utilized were a suspension of typhoid-paratyphoid bacilli and an autogenous, heat-killed, saline suspension of gonococci. A total of 50,000,000 organisms was the initial intravenous dose of the suspension of typhoid paratyphoid bacilli. Depending upon the reaction, each succeeding dose was increased by from 25,000,000 to 50,000,000 organisms. A total of five injections was given, at intervals of two or three days. Patients treated in this manner usually experienced chills and fever a few hours after the injections. Seven patients were treated with the typhoid paratyphoid vaccine, 2 of these were also given an autogenous gonococcal vaccine intravenously. Five patients were treated with gonococcal vaccine alone,

*The tests were done by the Wassermann Laboratory of the Massachusetts Department of Public Health.

and approximately the same doses were used as with the typhoid-paratyphoid vaccine. More severe reactions occurred after the administration of gonococcal vaccine than after that of typhoid paratyphoid vaccine. Although it was difficult to evaluate the results of vaccine therapy, patients with severe pains in the joints appeared to obtain more symptomatic relief than did those with only moderate pain.

Antigonococcal horse serum was given intravenously to 1 patient who had polyarthritus and gonococcal septicemia without endocarditis. Following the administration of serum his blood became sterile, but the prostatic secretion continued to show gonococci in stained smears. The use of antigonococcal horse serum and gonococcal vaccine in the treatment of gonococcal infections has been discussed in more detail elsewhere.⁷

In Group II, one or more knee joints were aspirated in 21 of the 26 patients. Cultures of all these synovial fluids were sterile. A wrist joint was aspirated in 2 cases. The culture of the aspirated material in 1 showed gonococci, the other was sterile. One infected shoulder joint was aspirated.

In Group III, the surgical treatment was necessary either because the synovial fluid was so thick that all of it could not be aspirated through a needle, or because of the presence of gonococci in the fluid. In many cases infected joints were aspirated several times, but gonococci were constantly present. They were eradicated from the joint cavity only after exposing the joint space and thoroughly washing it out with either warm saline or a 1:10,000 solution of bichloride of mercury. All the operative wounds were tightly closed immediately after this procedure. Synovial fluid often reaccumulated following the operation, but it was easily aspirated and was found to be sterile. We were unsuccessful in attempting to sterilize a knee joint in 1 patient by injecting potent antigonococcal horse serum directly into the synovial cavity.⁷ In 17 of the patients in this group knee joints were washed out, 2 had an elbow joint treated in this manner, and 1 had a hip joint opened. Gonococci were recovered from the synovial fluids in 16 cases.

RESULTS

Group I All 26 patients except 1 were treated in the hospital, the average stay being fifty days. Two of these died. One was a forty-two-year-old man who developed an acute glomerulonephritis due to a gonococcal infection and died from uremia. We have reported this case in a review of the renal complications of gonococcal infections.⁸ In the second fatal case, that of a twenty-one-year-old pregnant woman, the patient had an acute process in-

volving the right hip joint, she contracted pneumonia and died. Other complications included acute appendicitis (confirmed at operation), gonococcal septicemia, metastatic conjunctivitis and pregnancy. Upon leaving the hospital, 18 patients, or 75 per cent of the group, were completely free of all joint symptoms, with no limitation of motion and no roentgenological evidence of joint destruction, the 2 patients who died are not included here. Of the remaining 6, 1 ultimately had a complete bony ankylosis of a wrist joint, 1 had roentgenological evidence of destruction of one metatarsal joint, but with no limitation of function, 2 had a partial ankylosis of the wrist joints, and 2 had a residual soreness of joints of the lower extremities, which disappeared after several weeks.

Group II The average stay in the hospital for this group was fifty-three days. The aspirated synovial fluid from 22 of the patients was sterile. Infected fluid was aspirated from the shoulder joint of 1 individual and from the wrist joint of another. None of the group died. Four male patients had had a similar attack of arthritis in the past following a gonococcal infection. Two patients had a proved gonococcal septicemia and recovered without specific therapy. Two men had the skin lesions of keratoderma blenorrhagicum as a complication of their illness. Three patients had a metastatic sterile conjunctivitis, and 1 had iridocyclitis, resulting in loss of vision in one eye. One woman had a sterile meningitis on entry, the spinal fluid showed an increase in cells, but no organisms were demonstrated by smear or culture. Follow-up observations on these patients revealed that only 1 had a recurrence of joint symptoms, and this followed a second attack of gonococcal urethritis. Fourteen (48 per cent) of the 24 patients had complete recovery of joint function with no roentgenological evidence of joint destruction. Two patients had bony ankylosis of a wrist joint. One had a hyperflexion deformity of the toes. Another had destruction of the metatarsal joint of the first toe but no limitation of function. The remaining 6 patients had residual periarticular adhesions of the knee joints with slight limitation of motion on flexion (from 10 to 20 degrees) but no limitation on extension.

Group III Gonococci were recovered from the synovial fluid in 15 patients, while the fluid from 5 was sterile. The average stay in the hospital was sixty-one days. Two patients had keratoderma blenorrhagicum as a complicating skin lesion. One of this group of patients entered the hospital in diabetic coma, which was followed by bronchopneumonia and a purulent infection of an elbow joint. The presence of organisms in the synovial fluid of

the end of this time colonies of the gonococcus appear glistening, elevated and slightly opaque

As has been indicated above, the gonococcal complement-fixation test is of considerable value in the diagnosis of gonococcal arthritis. This test can be done on either blood serum or synovial fluid. In several patients in our series the first definite evidence that they had gonococcal arthritis was based on a positive gonococcal complement-fixation test. Myers and Keefer³ have discussed in detail the results of this test, and more recently Warren, Hinton and Bauer⁴ have advocated its more general use. The results of the gonococcal complement-fixation test of the blood and synovial fluid in the present series of cases are tabulated in Table 1.*

Table 1 *Results of Gonococcal Complement-Fixation Tests on Synovial Fluids and Blood Serums of Patients with Gonococcal Arthritis*

Synovial fluids	
Sterile fluids	
Positive	16
Negative	7
Doubtful	1
Infected fluids (gonococci)	
Positive	5
Negative	6
Blood serums	
Positive	47
Negative	5
Doubtful	2

The higher incidence of positive reactions on the blood is due to repeated tests' being done on the blood, whereas a comparable number of determinations could not be carried out on synovial fluid. Six of the eleven samples of synovial fluid with gonococci present gave negative fixation reactions. As we have explained elsewhere,⁵ this absence of antibodies accounts in part for the finding of the gonococci. We have found positive reactions as early as the first week of the disease, and some patients have continued to have positive tests from two to three years after all symptoms have subsided.

The aspiration and study of synovial fluid from patients with arthritis are of value in the differential diagnosis. The routine procedure after obtaining the fluid includes a total-cell count, gonococcal complement-fixation test, Wassermann test and culture. Myers, Keefer and Holmes⁶ have described the characteristics of the synovial fluid in gonococcal arthritis. They were able to divide such fluids into two groups, on the basis of the presence or absence of organisms. The average cell count was higher in the infected fluids which had a preponderance of polymorphonuclear leukocytes. In both types of fluid the total protein content was above normal, the nonprotein nitrogen value was the same as that of the blood, and the sugar content varied according

to the presence or absence of organisms, the number of leukocytes and the blood-sugar level. In our series the total cell count of the sterile fluids was usually below 25,000 per cubic millimeter. In 17 (24 per cent) of the cases we were able to isolate gonococci from the synovial fluid, and they were isolated from material obtained from a tendon sheath in 4 patients.

TREATMENT

In order to clarify the end results of treatment, the patients have been divided into three groups. Group I comprised 26 patients who were treated by medical means alone. In Group II, 24 patients had sufficient evidence of an effusion into one or more joint spaces to warrant aspiration of the synovial fluid in addition to medical therapy. Group III was composed of 20 patients whose joints were aspirated and also opened and followed by lavage.

The medical treatment of all these patients had for its objectives the maintenance of the patient's general nutrition, the prevention of pain and deformities, the restoration of full function of diseased joints through physiotherapy, and the control of the local genitourinary tract infection. The patients were given a diet sufficient in caloric content and supplemented with accessory food-derived substances. Some of them developed a severe hypochromic anemia during the course of their illness, which was corrected by administering ferrous sulfate, except in two cases where whole-blood transfusions were given. Joint pains were relieved by immobilization and by medication in the form of salicylates and opiates.

During the acute stage of the arthritis, few attempts were made to treat the local genitourinary infection, aside from vaginal douches. On several occasions when fever and joint pains had subsided, massage of the prostate gland was done. It was not unusual for patients to have a flare-up of their polyarthritis with fever following this maneuver.

Vaccines were administered intravenously to 11 patients. The vaccines utilized were a suspension of typhoid-paratyphoid bacilli and an autogenous, heat-killed, saline suspension of gonococci. A total of 50,000,000 organisms was the initial intravenous dose of the suspension of typhoid paratyphoid bacilli. Depending upon the reaction, each succeeding dose was increased by from 25,000,000 to 50,000,000 organisms. A total of five injections was given, at intervals of two or three days. Patients treated in this manner usually experienced chills and fever a few hours after the injections. Seven patients were treated with the typhoid paratyphoid vaccine, 2 of these were also given an autogenous gonococcal vaccine intravenously. Five patients were treated with gonococcal vaccine alone,

*The tests were done by the Wassermann Laboratory of the Massachusetts Department of Public Health.

GALLSTONE ILEUS

FRANKLIN G BALCH, JR, M.D.*

BOSTON

INTESTINAL obstruction due to gallstones is comparatively so uncommon that the average surgeon is not apt to encounter many such cases in the course of his practice. The writer has been fortunate enough to operate on such a patient and to assist at the operation on another during the last ten years.

This study is based upon 10 cases operated on at the Massachusetts General Hospital between 1898 and 1932, and upon 7 other cases operated on by colleagues who have allowed me to report them.

Frequency Scudder¹⁵ reported from the Massachusetts General Hospital, between 1898 and 1907, 121 cases of intestinal obstruction, only 1 of which was due to a gallstone. Richardson¹³ from the same hospital, from 1908 through 1917, reported 118 cases of intestinal obstruction, 1 of which was due to a gallstone. From 1918 through 1932, 8 cases due to gallstones have occurred out of a total of 263 cases of acute intestinal obstruction. Thus from 1898 through 1932 there were 10 cases among 502 obstructions, an incidence of 2 per cent. Barnard² reported that the London Hospital records for the thirteen years 1893 to 1905 showed that there were 14 cases of intestinal obstruction due to gallstones out of a total of 669 cases of intestinal obstruction due to all causes. The same author quotes Leichtenstern as reporting 41 cases of gallstone obstruction in a total of 1152 cases. As seen from Table 1, the incidence varies anywhere from 0.4 to 3.5 per cent.

Table 1 Incidence of Gallstone Ileus in Relation to All Cases of Intestinal Obstruction

	TOTAL CASES OF OBSTRUCTION	CASES OF GALLSTONE OBSTRUCTION	INCIDENCE %
Leichtenstern	1 152	41	3.5
Barnard ² (1910)	669	14	2.1
Souttar ¹⁶ (1925)	1 655	28	1.7
Vick ¹⁷ (1932)	3 625	47	1.3
Meyer and Spivack ¹¹ (1934)	505	2	0.4
M. G. H. (1937)	502	10	2.0

No recent estimate as to the total number of cases reported has been made. In 1914 Wagner¹⁸ reported 334 cases which he had been able to find up to that time in the literature and in his own practice. In 1922 Abbott and Hunt¹ reported 23 cases over an eight-year period. In the discussion of this paper, 8 more cases were added. Moore¹² in an excellent article in 1925 reported 4 cases and estimated that up to that time some 400 cases had been recorded.

Sex Women are much more prone to obstruction than men, in the proportion of about 15 to 1, whereas the incidence of gallstones in women and men is in about the proportion of 2 or 3 to 1. Why this difference occurs is difficult to explain. Moore's¹² 4 cases were all in women. Three of Abbott and Hunt's¹ cases were in women and 1 in a man. Of Martin's¹⁰ 3 cases, 2 were in women and 1 in a man. Of the 17 cases in this series, 16 were in women and 1 in a man.

Age This type of obstruction usually occurs in the later decades. The average age in this series was sixty-six, the youngest patient was in the fifth decade and the oldest in the ninth.

Mortality Partly because the disease occurs most commonly in later life, the mortality is high. In 1925 Souttar¹⁶ reported the results of acute intestinal obstruction from seven London hospitals for the years 1920 to 1925. Out of a total of 1655 cases of intestinal obstruction 28 were due to gallstones, with a mortality of 50 per cent. In 1932 Vick¹⁷ reported a series of 3625 cases of acute intestinal obstruction due to all causes, from the files of twenty-one hospitals in Great Britain between 1925 and 1930. Of these, 47 cases were due to gallstones, with a mortality of 70 per cent. The mortality from various other sources is shown in Table 2.

Table 2. Intestinal Obstruction from Gallstones

	NO. OF CASES	MORTALITY %
Lobstein ⁵	31	61
Courvoisier ⁶	125	44
Scheller ¹⁴	82	56
J. Hutchinson ⁷	—	50
Evans ⁸	15	40
Barnard-	14	61
Martin ¹⁰	3	0
Moore ¹²	4	75
Abbott and Hunt ¹	4	50
M. G. H. service cases	10	70
Private cases	7	57

An important factor in mortality is the length of duration of obstruction before operation is performed. Of this series of 17 cases, 8 were operated on after three days of obstruction and only 1 patient survived, whereas of the 9 cases operated upon during the first three days only 4 patients died.

Symptoms Obstruction due to gallstones gives a train of symptoms similar to obstruction due to other causes, namely pain, vomiting and obstipation. The obstruction from gallstones, however, is due to a true obstruction of the lumen of the bowel plus spasm, and not to a strangulation. As a result, the symptoms are often intermittent as

*Assistant in surgery, Harvard Medical School. Assistant surgeon, Massachusetts General Hospital.

a majority of the patients is reflected in the end results. Only 3 patients (15 per cent) ultimately had no limitation of motion of joints. Six had an ankylosis of one joint with less than 10 degrees of joint motion. These included one hip joint, one elbow joint and four knee joints. Three individuals were capable of only 50 degrees of motion of one knee joint. Eight patients had peri-articular fibrosis of one knee joint with from 10 to 15 degrees' limitation of motion on flexion, but with capacity for full extension.

DISCUSSION

The ultimate therapeutic goal for the arthritic patient is the restoration of joint function, and end results should be measured accordingly. It is misleading to state that a particular form of therapy resulted in relief of symptoms, improvement or cure when nothing is said of the use a patient has of his joints. Furthermore, it is often difficult to evaluate the methods of treatment because of an arbitrary division into acute and chronic stages.

Since gonococcal arthritis is due to a specific organism, the ultimate outcome so far as joint function is concerned may be dependent on the numbers of gonococci in the joint tissues. Individuals with an acute arthritis of only a few weeks' duration may have a loss of joint function if large numbers of organisms are present, whereas an arthritis lasting for weeks or months may not result in joint destruction if the effusion is sterile. A large measure of success in the therapy of gonococcal arthritis is dependent on an early diagnosis and the eradication of the organism from the joint cavities.

During the last few years a number of favorable reports have appeared advocating the use of hyperthermia in the treatment of gonococcal arthritis. Hench^{9, 10} and others^{11, 12} have recently reviewed the literature as to this form of therapy. The most favorable results with fever therapy were apparently obtained in patients with acute gonococcal arthritis. We have had no experience with this type of therapy, but believe that it merits further trial.

A closer analysis of our series of 70 patients reveals that 5 had serious involvement of a wrist joint, 3 of these developed complete ankylosis, while 2 had residual soreness and pain on motion that lasted for several weeks. It is apparent that even though the wrist joint is infected, surgical intervention and drainage is highly impracticable. This site of arthritis appears to be highly amenable to fever therapy.

Our experience and that of others is that the knee joint is the one most frequently involved in gonococcal arthritis. Thus, of the twenty-four cases

in which joints were treated by aspiration with out drainage, the knee joint was involved in twenty one. In the twenty cases in which joints were surgically drained and lavaged, the knee joint was involved in eighteen. Of considerable interest is the fact that the poorest end results were obtained in patients whose joints were infected. In some of these patients other types of arthritis were first suspected, especially acute rheumatic fever, so that considerable destruction had ensued before they were opened.

There has been a recurrence of arthritis in 2 of the 70 patients. Both were men, and in each case joint symptoms were precipitated by a recurrent urethral infection three months after discharge from the hospital. Three of the women have had subsequent normal pregnancies, with no exacerbation of joint symptoms.

SUMMARY

We have observed 70 patients with gonococcal arthritis during the past three years. The criteria for making the diagnosis of this type of arthritis are discussed. Group I constituted 26 patients who were treated by medical means only, Group II comprised 24 patients who had an effusion into one or more joints which necessitated aspirations of the synovial fluid, Group III included 20 patients with purulent joint effusions which required surgical drainage. Follow-up studies revealed that 20 of the 26 patients in Group I were free of all joint symptoms, with no limitation of motion. Fourteen of the 24 patients in Group II showed no limitation. Of the 20 patients in Group III, only 3 had a return of complete function of their joints.

ness anywhere. The white blood cell count was 16,600, the temperature 101.5°F, the pulse rate 120 and the respirations 32. No x ray photographs were taken.

Operation was performed under ether anesthesia as soon as possible. The patient's condition was poor. A midline suprapubic incision was made, which was followed by evisceration of a large portion of the intestines. The obstruction was caused by a large, immovable gallstone with the wall of the bowel contracted about it. The exact point of obstruction could not be determined. The intestine was opened in two places by 1-cm incisions and a large amount of liquid fecal material was withdrawn. During this procedure salt solution was constantly passed over the intestines. The openings were closed with silk sutures following the removal of the gallstone. The wound was closed with through and through silkworm gut sutures. No effort was made to close the skin. The patient died shortly after the operation.

Case 2 A housewife of 71 entered the Massachusetts General Hospital on August 19, 1915, with a history of generalized abdominal pain and fecal vomiting for 2 days with no bowel movement for 3 days. She had been treated with brisk catharsis without either fecal or gas results.

Examination showed a very sick old woman who was unable to give her own history. The abdomen was distended and tender throughout, with visible peristalsis. It was tympanic except in the left flank. No masses or spasm could be elicited. The white-blood cell count was 11,000, the temperature 100.8°F, the pulse rate 118 and the respirations 24. No x ray photographs were taken.

Under novocain anesthesia, laparotomy was performed through a 10-cm. incision just to the left of the midline. The large bowel and most of the small bowel were contracted. The stomach was markedly dilated. A large "fecolith" was found in the upper end of the jejunum. This was removed through a 5-cm. incision, which was closed with a double row of Pagenstecher sutures. The ominal wound was closed without drainage. The patient was in very poor condition following operation. She died in 24 hours. An autopsy showed chronic cholecystitis, with necrosis of the gall bladder wall and wall of the duodenum, wounds from operation for intestinal obstruction, due to a large concretion in the small intestine, probably a gallstone, arteriosclerosis of the mitral valve, slight, with stenosis, hypertrophy and dilatation of the heart, hemorrhagic pneumonia of the lungs, slight chronic pleuritis, left, carcinoma of the stomach, possibly originating in a congenital malformation of the nature of an accessory pancreas, scoliosis.

Case 3 A housewife of 46 entered the Massachusetts General Hospital on February 11, 1919, complaining of per abdominal pain of 2 weeks duration. The pain was colicky and was associated with nausea and vomiting, which occurred ten or twelve times a day. Enemas produced both good fecal and gas results. On the morning of entrance the vomiting was fecal. The patient had had two similar though milder episodes 10 years and 1 year before entrance.

Examination showed a markedly obese woman, quite anorectic. The patient had been given ¼ gr of morphine 4 hours before entry. The tongue was dry and red. The abdomen was tender throughout, with spasm in the right upper and lower quadrants. The left half of the abdomen showed no spasm. The white-blood cell count was 14,400, the temperature 97.6°F, the pulse rate 104 and the respirations 16. No x ray photographs were taken.

Laparotomy was performed shortly after admission. The bowel was adherent in the pelvis. No collapsed bowel was seen. There was dilatation of the large as well as of the small bowel. Owing to the patient's poor condition, further exploration was not done. The adhesions were freed and the patient was returned to the ward almost moribund. She died a few hours after operation. Autopsy showed the following: cholelithiasis, pericholecystitis, with necrosis of the gall bladder and the wall of the duodenum, occluding gallstone in the ileum, acute intestinal obstruction, slight fibrinous peritonitis, fatty metamorphosis of the liver, operation wound from laparotomy.

Case 4 A housewife of 68 entered the Massachusetts General Hospital on March 9, 1922, complaining of generalized abdominal pain, intermittent and associated with vomiting of 3 days duration. At entrance the patient felt better than she had for 24 hours. Her bowels had moved 3 days before entrance, but not since then even with enemata.

Examination showed a moderately tense, considerably distended abdomen, with visible peristalsis. The white-blood cell count was not taken, the temperature was 97°F, the pulse rate 90 and the respirations 18. No x ray photographs were taken.

An immediate operation was done. There was considerable free turbid fluid in the peritoneal cavity. In the pelvis there were several loops of intestine covered with fibrin. A gallstone 4 by 2 by 2 cm., movable only with considerable difficulty, was found in the ileum. This was removed, and the incision was closed with a double layer of silk. Palpation of the gall bladder showed a mass of adhesions. A cigarette drain was placed in the pelvis.

The patient made an uneventful convalescence, and a year later reported that she had had no further trouble except for some pain in the lower end of the scar, where there was a definite hernial ring.

Case 5 A housewife of 70 entered the Massachusetts General Hospital on October 11, 1923, complaining of intermittent umbilical pain associated with vomiting of several weeks duration. There had been two or three attacks a week. Her bowels had moved every day following the use of cathartics.

Examination showed a general moderate tenderness throughout the abdomen, with only slight distention and occasional visible and audible peristalsis. The white-blood cell count was 22,400, the temperature 97°F, the pulse rate 120 and the respirations 20. No x ray photographs were taken.

Operation was performed through a left rectus incision and a gallstone measuring about 3 by 1.5 cm. was found impacted in the ileocecal valve. An attempt to force the stone through the valve was unsuccessful. It was removed through the terminal ileum, with closure of the incision by means of two rows of sutures, one of catgut and one of silk. Examination of the gall-bladder area showed multiple adhesions. The abdomen was closed without drainage. There was considerable nausea and vomiting following the operation and there was infection of the wound. This gradually cleared up, and the patient was discharged 19 days after operation.

Two years later she re-entered the hospital with what appeared clinically to be carcinoma of the pancreas. This impression was confirmed at operation, when the gall bladder was found to be buried in adhesions which puckered the duodenum firmly to it. No biopsy was taken. The patient made a surprisingly uneventful convalescence.

the spasm relaxes and the stone proceeds farther down the bowel. As a certain amount of gas may get by, distention may not be a prominent factor and the patient may continue to pass small amounts of gas by rectum. Since the lumen of the small bowel decreases slightly in diameter as it approaches the cecum, obstruction by a large stone will eventually be complete. Smaller ones may go through the ileocecal valve, if so, they are readily passed by rectum. Barnard² states that stones of less than 2.5-cm diameter will pass spontaneously, and reports that MacLagan⁹ in 1888 had a patient with four attacks of intestinal obstruction with the spontaneous passage of four 2.5-cm stones. He quotes Faber, Abt, Gutterbock and Hahn concerning sizes and points of obstruction. The largest stone reported was 6 cm in diameter and obstructed the upper jejunum. Drew⁵ reported a case where the stone measured 6 by 3 by 10 cm, this patient died. The largest stone in the Massachusetts General Hospital series was 5 cm in diameter and obstructed the terminal ileum.

Diagnosis A positive diagnosis of obstruction due to gallstones is frequently very difficult, but the diagnosis of intestinal obstruction can readily be made from the symptoms. A history of preceding gall-bladder distress or of epigastric pain, associated with vomiting and then relieved for a period, only to recur with pain near the umbilicus and with renewed vomiting, should make one very suspicious of gallstone obstruction. An x-ray of the abdomen is often of value in showing a shadow suggestive of gallstones. Of the 6 cases in this series in which an x-ray was taken, stones were reported in 3. The white-blood-cell count, as in other cases of intestinal obstruction, is usually elevated, but is apt not to be so high as in obstruction due to strangulation.

Mode of Entrance into the Gastrointestinal Tract Most writers agree that the majority of stones pass by way of a fistula between the gall bladder and the duodenum. Courvoisier⁴ stated that in 30 fatal cases, 28 were due to fistula between the gall bladder and duodenum while 2 were due to fistula between the gall bladder and colon. Moore¹² quotes Murphy as reporting 70 cases in which the route of the gallstone was traced. Of these 36 occurred through a gall-bladder-duodenum fistula, 25 through a gall-bladder-ileum fistula, 1 through a duodenum-colon fistula, and 7 through a common duct-duodenum fistula. Of the 7 cases in our series which were autopsied, all were found to have gall-bladder-duodenum fistulas.

Treatment As in any case of acute intestinal obstruction, early diagnosis and operation is imperative. As Richardson¹³ said concerning intestinal obstruction in general, "Operation should be

based on suspicion rather than on certainty." Delay means death. Intravenous saline is needed in order to replace the chlorides lost by vomiting. As a rule the bowel is not gangrenous, so that resection is unnecessary. The stone should be pushed back up the bowel, which can then be opened in a healthy area. On opening the bowel it is advisable that the incision be made in a longitudinal, and sutured in a transverse, direction, as this tends not to constrict the diameter of the bowel. In removing a stone from the bowel, the segment containing the stone should be brought out of the abdominal cavity and well walled off before any incision is made. Gloves and instruments should be changed before the bowel is returned to the abdominal cavity and the wound closed. An ileostomy above the site of obstruction is usually unnecessary, and we believe that it tends to increase the mortality. Unless there is gross contamination of the peritoneal cavity, drainage should not be carried out. We believe that Wangenstein drainage for about forty-eight hours after operation is advisable, since it tends to prevent distention and makes the patient more comfortable. Of the 17 cases in this series, 1 was drained and 3 had an ileostomy. One case was not operated on owing to the patient's poor general condition.

SUMMARY AND CONCLUSIONS

- 1 Seventeen cases of obstruction of the small bowel due to gallstones are reported.
- 2 These occurred most commonly in elderly women.
- 3 Obstruction from this cause differs from the usual type of obstruction of the small bowel in that it is often intermittent in character and that patients may pass gas or even feces during the quiescent periods of an attack.
- 4 Early diagnosis and operation is imperative in this type of obstruction.
- 5 X-ray films should be made, as they may be very important diagnostic aids.
- 6 Ileostomy is usually not necessary, and may be harmful.
- 7 Drainage of the abdominal cavity is as a rule unnecessary.

CASE REPORTS

Case 1 A housewife of 40 entered the Massachusetts General Hospital on August 31, 1899, with a history of a sudden attack of crampy epigastric pain five days before entry. The pain was very severe and continued until the time of entrance, and was associated with vomiting of a considerable amount of dark-colored fluid. She stated that she had had three small bowel movements since the onset. On the day of entrance she felt more comfortable.

Examination showed an obese woman with a dry, black tongue and cold, clammy extremities. The abdomen was markedly distended with no localized tender

ness anywhere. The white blood cell count was 16,600, the temperature 101.5°F, the pulse rate 120 and the respirations 32. No x ray photographs were taken.

Operation was performed under ether anesthesia as soon as possible. The patient's condition was poor. A midline suprapubic incision was made, which was followed by evisceration of a large portion of the intestines. The obstruction was caused by a large, immovable gallstone with the wall of the bowel contracted about it. The exact point of obstruction could not be determined. The intestine was opened in two places by 1-cm incisions and a large amount of liquid fecal material was withdrawn. During this procedure salt solution was constantly passed over the intestines. The openings were closed with silk sutures following the removal of the gallstone. The wound was closed with through and through silk worm gut sutures. No effort was made to close the skin. The patient died shortly after the operation.

Case 2 A housewife of 71 entered the Massachusetts General Hospital on August 19, 1915, with a history of generalized abdominal pain and fecal vomiting for 2 days with no bowel movement for 3 days. She had been treated with brisk catharsis without either fecal or gas results.

Examination showed a very sick old woman who was unable to give her own history. The abdomen was distended and tender throughout, with visible peristalsis. It was tympanic except in the left flank. No masses or spasm could be elicited. The white-blood cell count was 11,000, the temperature 100.8°F, the pulse rate 118 and the respirations 24. No x ray photographs were taken.

Under novocain anesthesia, laparotomy was performed through a 10-cm incision just to the left of the midline. The large bowel and most of the small bowel were contracted. The stomach was markedly dilated. A large "fecalith" was found in the upper end of the jejunum. This was removed through a 5-cm incision, which was closed with a double row of Pagenstecher sutures. The abdominal wound was closed without drainage.

The patient was in very poor condition following operation. She died in 24 hours. An autopsy showed chronic pericholecystitis, with necrosis of the gall-bladder wall and the wall of the duodenum, wounds from operation for intestinal obstruction, due to a large concretion in the small intestine, probably a gallstone, arteriosclerosis chronic endocarditis of the mitral valve, slight, with stenosis hypertrophy and dilatation of the heart, hemorrhagic edema of the lungs, slight chronic pleuritis, left, carcinoma of the stomach, possibly originating in a congenital malformation of the nature of an accessory pancreas, scoliosis.

Case 3 A housewife of 46 entered the Massachusetts General Hospital on February 11, 1919, complaining of upper abdominal pain of 2 weeks duration. The pain was colicky and was associated with nausea and vomiting, which occurred ten or twelve times a day. Enemas produced both good fecal and gas results. On the morning of entrance the vomiting was fecal. The patient had had two similar though milder episodes 10 years and 1 year before entrance.

Examination showed a markedly obese woman, quite comatose. The patient had been given $\frac{1}{4}$ gr of morphine 2 hours before entry. The tongue was dry and red. The abdomen was tender throughout, with spasm in the right upper and lower quadrants. The left half of the abdomen showed no spasm. The white-blood cell count was 17,400, the temperature 97.6°F, the pulse rate 104 and the respirations 16. No x ray photographs were taken.

Laparotomy was performed shortly after admission. The bowel was adherent in the pelvis. No collapsed bowel was seen. There was dilatation of the large as well as of the small bowel. Owing to the patient's poor condition, further exploration was not done. The adhesions were freed and the patient was returned to the ward almost moribund. She died a few hours after operation. Autopsy showed the following: cholelithiasis, pericholecystitis, with necrosis of the gall bladder and the wall of the duodenum, occluding gallstone in the ileum, acute intestinal obstruction, slight fibrinous peritonitis, fatty metamorphosis of the liver, operation wound from laparotomy.

Case 4 A housewife of 68 entered the Massachusetts General Hospital on March 9, 1922, complaining of generalized abdominal pain, intermittent and associated with vomiting of 3 days duration. At entrance the patient felt better than she had for 24 hours. Her bowels had moved 3 days before entrance, but not since then even with enemas.

Examination showed a moderately tense, considerably distended abdomen, with visible peristalsis. The white-blood cell count was not taken, the temperature was 97°F, the pulse rate 90 and the respirations 18. No x ray photographs were taken.

An immediate operation was done. There was considerable free turbid fluid in the peritoneal cavity. In the pelvis there were several loops of intestine covered with fibrin. A gallstone 4 by 2 by 2 cm., movable only with considerable difficulty, was found in the ileum. This was removed, and the incision was closed with a double layer of silk. Palpation of the gall bladder showed a mass of adhesions. A cigarette drain was placed in the pelvis.

The patient made an uneventful convalescence, and a year later reported that she had had no further trouble except for some pain in the lower end of the scar, where there was a definite hernial ring.

Case 5 A housewife of 70 entered the Massachusetts General Hospital on October 11, 1923, complaining of intermittent umbilical pain associated with vomiting of several weeks duration. There had been two or three attacks a week. Her bowels had moved every day following the use of cathartics.

Examination showed a general moderate tenderness throughout the abdomen, with only slight distention and occasional visible and audible peristalsis. The white-blood cell count was 22,400, the temperature 97°F, the pulse rate 120 and the respirations 20. No x ray photographs were taken.

Operation was performed through a left rectus incision and a gallstone measuring about 3 by 1.5 cm. was found impacted in the ileocecal valve. An attempt to force the stone through the valve was unsuccessful. It was removed through the terminal ileum, with closure of the incision by means of two rows of sutures, one of catgut and one of silk. Examination of the gall bladder area showed multiple adhesions. The abdomen was closed without drainage. There was considerable nausea and vomiting following the operation and there was infection of the wound. This gradually cleared up, and the patient was discharged 19 days after operation.

Two years later she re-entered the hospital with what appeared clinically to be carcinoma of the pancreas. This impression was confirmed at operation, when the gall bladder was found to be buried in adhesions which puckered the duodenum firmly to it. No biopsy was taken. The patient made a surprisingly uneventful convalescence.

and was relieved of her symptoms. The further course of this case is not known.

Case 6 A housewife of 75 entered the Massachusetts General Hospital on January 25, 1927, complaining of indigestion of 1 day's duration, associated with almost constant vomiting from onset to admission. This was accompanied by slight abdominal pain and cramplike pain in both lower extremities. Shortly before admission she noticed that the vomitus smelt like feces. This fact was confirmed at entrance. She had a small stool before entry.

Examination showed a soft, pendulous abdomen, not distended, without visible or audible peristalsis. The white-blood cell count was 24,000, the temperature 100°F, the pulse rate 110 and the respirations 24. No x ray photographs were taken.

Through a right rectus incision the abdomen was opened, and the entire small intestine was found to be dilated. The cecum was collapsed. A gallstone about 5 cm. in diameter was felt in the terminal ileum. This was removed, and the wound in the bowel was closed transversely.

Following operation, the patient took fluids poorly. Ten days after operation the wound broke down and drained profusely. This gradually cleared up with the use of Dakin's solution. The patient was discharged about 6 weeks after operation. A note some 5 months after operation stated that she was still weak and unable to report for any examination.

Case 7 A housewife of 67 entered the Massachusetts General Hospital on August 17, 1927, complaining of upper abdominal pain and vomiting of 5 days' duration. The vomiting was continuous and fecal. Her bowels had moved once since the onset of symptoms. The pain was generalized throughout the abdomen and very severe.

Examination showed generalized abdominal distention and tenderness without much spasm. There was no visible peristalsis but slight audible peristalsis over the left side of the abdomen. The white-blood cell count was not taken. The temperature was 99°F, and the respirations 30. No x ray photographs were taken.

Upon opening the abdomen through a right rectus incision, several loops of dilated small intestine were encountered. In the right lower quadrant the bowel was collapsed. A gallstone about 4 cm. in diameter was found in the lower ileum. The stone was removed, and the intestine was closed in two layers. An ileostomy was performed just above the line of suture.

The patient did fairly well for 24 hours after operation, when the pulse became elevated and signs of recurrent obstruction appeared. She died before any further operation could be done. No autopsy was done.

Case 8 A housewife of 59 entered the Massachusetts General Hospital on January 6, 1930, complaining of sharp mid-epigastric pain of 1 day's duration. For about 3 weeks prior to entry she had felt bloated after eating, but had had no pain. Her present attack was localized in the "pit of the stomach." She felt nauseated but did not vomit. There was no history of any previous gastrointestinal upset.

Examination showed a moderately distended abdomen without spasm but with a mild, diffuse tenderness around the umbilicus. Peristaltic sounds were scarce. She was admitted to the hospital for observation. The vomiting continued and became fecal, and was associated with an increase in abdominal distention and in audible peristalsis. The white-blood cell count was 15,750, the temperature

102°F, the pulse rate 100 and the respirations 24. A flat abdominal x ray plate showed no evidence of stone.

Operation was performed through a right rectus incision on the second day after admission. A gallstone about 2 cm. in diameter, faceted at either end and causing partial obstruction, was found in the ileum. This was removed through a longitudinal incision, which was closed transversely. No palpation of the gall-bladder area was done. A second smaller stone was palpated in the sigmoid and was delivered through the rectum.

The patient made an entirely uneventful convalescence, and 5 months later was entirely well with no symptoms. She was readmitted January 14, 1931, with acute cholecystitis. Four days after admission signs of peritonitis and pleurisy developed. Under novocain anesthesia a localized abscess was opened. She failed rapidly, dying 24 hours after operation. Autopsy showed the following: acute cholecystitis with perforation, general peritonitis, gall bladder-duodenum fistula, duodenal diverticulum, acute pleuritis, acute interstitial pancreatitis, obesity, arteriosclerosis, slight hypertrophy of the heart.

Case 9 An 80 year-old man was admitted to the Massachusetts General Hospital on October 17, 1930, complaining of abdominal pain associated with nausea and vomiting of 24 hours duration. The pain was sufficient to wake him up and had been increasing prior to entrance. It was localized mostly in the epigastrium. On entrance 37 oz of fecal matter was removed by gastric lavage.

Examination showed moderate tenderness without spasm in the epigastrium and along the course of the descending colon and cecum. The white blood count was not taken. The temperature was 99°F, the pulse rate 80 and the respirations 16. No x ray photographs were taken.

Laparotomy was performed through a right rectus incision. The small intestine was found to be dilated above a mass the size of a golf ball, which was situated 60 cm. from the ileocecal valve. A gallstone was removed, and the intestine was sutured in two layers longitudinally.

The patient was in poor condition throughout the operation, and died in 24 hours, apparently from uremia. Permission for an autopsy was not obtained.

Case 10 A housewife of 77 entered the Massachusetts General Hospital on November 3, 1932, complaining of vomiting and epigastric pain of 1 week's duration, not very severe but constant. After 3 days the pain had shifted to the right lower quadrant, where it persisted until entrance. The vomiting was almost constant for 3 days prior to entry. Her bowels had moved several times since the onset of the attack.

Examination showed an enormously distended abdomen, tympanic throughout, with slight tenderness and spasm in the right lower quadrant. The white blood count was 10,800, the temperature 99°F, the pulse 80 and the respirations 20. No x ray photographs were taken.

Laparotomy was performed through a midline incision. The ileum was dilated and covered with fibrin in the region of the appendix. The appendix, though covered with fibrin, was otherwise normal. A large gallstone about the size of a squash ball was removed from the terminal ileum, and an ileostomy was performed above the line of suture.

Following operation, the patient never regained consciousness and rapidly died. Autopsy showed the following: cholecystoduodenostomy, spontaneous, peritonitis, localized, bronchopneumonia, early, cardiac hypertrophy and dilatation, diverticula of duodenum and colon, arteriosclerosis, aortic, coronary and renal (marked) leiomyomas of the uterus, obesity.

Case 11 A housewife of 62 entered the Faulkner Hospital November 30, 1936, having been referred to me by Dr. Willis M. Stevenson of North Easton. Three days before entry she had complained of nausea and vomiting with a grumbling pain at the level of the umbilicus. This subsided so that she slept well the first night. The following day she was up and around, but vomited at intervals without recurrence of the pain. Her bowels moved twice on the day of onset but not since then, nor had she passed any gas by rectum. She had had a similar episode two years before, lasting for 4 or 5 days, with spontaneous remission. There had been no history of food idiosyncrasy.

Examination showed a well nourished woman, slightly obese, in no discomfort but considerably dehydrated. The abdomen was not distended. Peristalsis appeared to be normal. There was no localized tenderness anywhere in the abdomen. The white blood count was 17,000, the temperature 99.4°F, the pulse 87 and the respirations 20. She was given intravenous saline to replace the lost fluids, and the day after admission a flat abdominal x-ray plate was taken so that we could see whether there were any dilated loops of bowel. This plate showed a definitely calcified area on the left side of the pelvis, very suggestive of a gallstone. The patient continued to have nausea and occasional pain and was operated upon 2 days after admission. This was done through a right paramedian incision. There was a moderate amount of clear fluid in the peritoneal cavity. On the left side of the abdomen a large mass was felt. This proved to be bowel containing an impacted gallstone. The gallstone was removed, and the incision closed with two layers of catgut. The abdomen was closed without drainage. The gallstone weighed 20.3 gm. and measured 4 cm. in the largest diameter.

There was a slight infection of the subcutaneous fat. The patient was discharged in 2 weeks following the operation, taking nourishment satisfactorily. When seen 3 months after operation she felt entirely normal.

Case 12 A housewife of 70, who was operated on by Dr. F. G. Balch, Sr., and me, entered the Baker Memorial Hospital on November 26, 1932. She complained of severe, steady mid-abdominal pain of 3 days duration. It radiated over both upper quadrants into the front and back of the chest, but was not associated with nausea or vomiting. On the day of admission she became nauseated and vomited. The pain recurred with great intensity and required morphine for its control. Two years before she had complained of severe pain between the shoulder blades, not associated with nausea or vomiting but with severe jaundice. This subsided spontaneously in about 1 month. There was a recurrence of similar but milder symptoms 2 months later with spontaneous remission.

Examination showed a thin, undernourished woman with a faint icteric tinge to the skin. There was slight abdominal distention and no visible peristalsis. There was slight tenderness in the right upper quadrant. Audible peristalsis was somewhat increased. A flat abdominal plate showed a laminated calculus, presumably obstructing a loop of small bowel.

Laparotomy was performed through a right rectus incision. There was no free fluid in the peritoneal cavity. A mass about 4 cm. in diameter was felt in the terminal ileum. This proved to be a gallstone, which was removed, the incision being closed with a double layer of catgut. There was a dense mass of adhesions in the region of the gall bladder. The wound was closed without drainage.

The patient made an entirely uneventful convalescence.

Case 13 A housewife of 72 who was operated upon by Dr. E. L. Young, Jr., entered the Lawrence Memorial

Hospital on June 22, 1927, complaining of generalized abdominal pain associated with nausea and vomiting of 5 days duration. She had had bowel movements up to the night prior to entrance.

Examination showed a very sick looking old woman with a markedly distended abdomen and increased peristalsis. The vomitus was fecal. No white blood count was taken. The temperature was 98.6°F, the pulse 94 and the respirations 22.

Laparotomy was performed under novocain anesthesia. Satisfactory exploration was possible and revealed a mass about 7 by 4 cm. apparently in the ileum. A gallstone measuring 2 by 2 cm. was removed from the ileum, and the incision was closed with a double layer of catgut. The abdominal wound was closed without drainage.

She died about 48 hours after operation. Autopsy showed a fistula between the gall bladder and the duodenum.

Case 14 A housewife of 83 was referred to the Faulkner Hospital by Dr. D. L. Lionberger. She entered on September 24, 1936, complaining of vomiting of 6 days duration. At the onset of her illness she complained of upper abdominal, crampy pain associated with diarrhea, nausea and vomiting. The diarrhea and pain subsided, but the nausea and vomiting continued. She refused to enter the hospital until the 6th day of her illness.

Examination showed a feeble old woman with a dry mouth and tongue. The vomitus was definitely fecal. The nonprotein nitrogen was markedly elevated. The white blood count was 11,500, the temperature 98°F, the pulse 110 and the respirations 37. No definite diagnosis was made. The differential diagnosis lay between intestinal obstruction and uremia. The abdomen was not distended but high pitched peristalsis was audible. Her condition rapidly grew worse and she died 4 days after admission. Surgical exploration was not deemed advisable because of the patient's condition.

Autopsy showed a large, egg sized gallstone causing obstruction about 90 cm. above the ileocecal valve. There was a direct fistula between the gall bladder and the duodenum.

Case 15 A housewife of 67, who was operated upon by Dr. E. M. Daland, entered the Baker Memorial Hospital on April 12, 1934, complaining of pain in her stomach and vomiting of 10 days duration. Nine weeks before entry there had been a severe attack of epigastric pain and a feeling of substernal pressure. Since then there had been grumbling discomfort. Ten days before admission there was marked vomiting. Five days before admission the patient felt better, but the following day the pain became much more severe. Three days before entry an enema produced good fecal and gas results.

Examination showed a very much distended abdomen with tympany over the entire area. There was no tenderness or spasm. The white blood count was 12,900, the temperature 98°F, the pulse 80 and the respirations 20. An x-ray photograph taken on the day of admission suggested partial obstruction of the colon, probably in the region of the descending portion.

On the day of admission a laparotomy was performed under novocain anesthesia through a right muscle splitting incision. The cecum and small bowel were not particularly distended. A No. 30 catheter was sutured into the cecum.

The cecostomy did not function for 48 hours, but gas was passed following a rectal enema. One week after operation there was considerable increase in abdominal distention, and an ileostomy was performed. At that

time there was cloudy fluid in the abdominal cavity. The fluid showed colon bacilli on culture. The patient's condition gradually became worse and she died 12 days after admission. Autopsy showed the following: colloid adenocarcinoma of the gall bladder with metastases to mesenteric glands, cholecystoduodenal fistula, intestinal obstruction, gallstone in ileum, ulceration of jejunum and ileum, traumatic, with perforation and pelvic peritonitis, operative wounds from ileostomy and cecostomy, pulmonary embolism and infarction, renal infarction, thrombosis of suprarenal artery, polyposis of colon, arteriosclerosis, coronary and aortic, slight, pleuritis, chronic fibrous, bilateral, obesity.

Case 16 A housewife of 42, who was operated upon by Dr. H. H. Faxon, entered the Baker Memorial Hospital on July 13, 1931, complaining of abdominal pain of 3 days duration. Three nights before admission she suddenly had cramp-like, severe, non-radiating pain in the mid-epigastrium associated with nausea and vomiting. The severe pain persisted until entry, being localized a little more toward the umbilicus. Her bowels had moved with the help of saline cathartics until the day of entry. Two enemas on the morning of entrance produced no results. For 3 years she had had intermittent attacks of right upper-quadrant pain, radiating on one occasion to the back and associated with nausea and vomiting, but no jaundice.

Examination showed a rather obese middle-aged woman having attacks of cramp-like lower epigastric pain every 5 minutes which lasted about 1 minute. The abdomen was not distended. There was very slight tenderness in the gall bladder area. The white blood count was 17,000, the temperature 90°F, the pulse 90 and the respirations 21. As the patient was in fairly good condition, conservative treatment was decided upon. A few hours later she suddenly collapsed and was operated upon immediately.

Laparotomy was performed through a lower abdominal incision. A firm mass was felt in the ileum about 60 cm. from the ileocecal valve, it was round and about the size of a golf ball. The bowel was opened and a gallstone removed. The wound was closed without drainage.

The patient's condition was poor throughout the operation, and in spite of a transfusion she died a few hours following operation. No autopsy was done.

Case 17 A housewife of 78 who was operated upon by Dr. A. W. Allen entered the Baker Memorial Hospital on May 12, 1934. She had been known to have a gall bladder full of stones for about 9 years. Three days before admission she had severe right upper-quadrant discomfort, with radiation to the scapula, lasting for 20 minutes. The morning of entrance she complained of gas pains, which were not relieved by a normal bowel movement. About noon the pain became colicky in character and occurred every 5 minutes, lasting about 15 seconds at each attack. An enema gave no relief and caused no results. Nausea and vomiting continued throughout the day.

Examination showed tenderness on the left side of the abdomen near the umbilicus with slight spasm. The

white blood count was 11,000, the temperature 98°F, the pulse 88 and the respirations 16. Conservative treatment was advised. The day following admission, while in the x-ray department, she became nauseated but did not vomit.

An x-ray film taken 9 months before admission had shown two large gallstones in the right upper quadrant, while one taken on admission showed one gallstone in the gall-bladder area with another lying opposite the left ischial spine. An x-ray film taken 2 days after admission showed a moderately dilated loop of what appeared to be the jejunum extending down to the stone.

Two days after admission a laparotomy was performed through a left paramedian incision. The obstruction was about the size of a plum and was gently moved for 8 cm. in the intestine. The bowel was opened through a longitudinal incision, a gallstone was removed, and the bowel was sutured transversely. The abdomen was closed without drainage. The obstruction apparently occurred at the mid-ileum.

Following operation, the patient's temperature rose to 105°F and she showed signs of atelectasis. A transfusion was given, the patient's condition improved, and she was discharged relieved on June 9.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 2, 1938

A STATED meeting of the Council was held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, February 2, at 10.30 a m. The president, Dr Channing Frothingham, Suffolk, was in the chair, and 180 Councilors were present (Appendix No 1)

After the meeting was called to order by the President, he called upon the Secretary to present the record of the last meeting. The Secretary stated that the record of the meeting, held on October 6, 1937, was published in the *New England Journal of Medicine* for October 28, 1937. The President declared that, there being no objections, the report would be considered approved as published.

The President read the obituary of Dr John M Doran of Chelsea, a Councilor, who had died since the last meeting.

DR. JOHN MICHAEL DORAN died at the Chelsea Memorial Hospital, November 13, 1937. He was in his fifty third year.

After attending both Chelsea and Charlestown schools he received his degree from the Baltimore Medical College in 1907. He interned at the Maryland General Hospital.

Dr Doran was a member of the American Medical Association and of the Massachusetts Medical Society, being a member of the Council at the time of his death. He was president of the staff of the Chelsea Memorial Hospital.

His twin sons survive him.

Following the reading of the obituary the Council stood in silence in tribute to the memory of Dr Doran.

The Council voted to approve the report of the Auditing Committee as submitted by Dr Edmund H Robbins, Middlesex South (Appendix No 2).

Dr Charles S Butler proceeded to present the Treasurer's Report (Appendix No 3), which was accepted by vote.

REPORTS OF STANDING COMMITTEES

Membership and Finance

The report of the committee, as is customary, was divided into two parts, the first dealing with changes in membership (Appendix No 4). This report was adopted and the recommendations approved. The second part of the report (Appendix No 5) contained the recommendations for appropriations for the year 1938. The budget as submitted was approved by vote.

Arrangements

In the absence of the chairman, the report of the committee was read by the Secretary (Appendix

No 6). This report announced the dates of the 1938 annual meeting to be May 31, June 1 and June 2, at the Hotel Bradford in Boston. The report was accepted and the recommendations adopted.

Ethics and Discipline

The report of the committee was presented by the chairman, Dr David Cheever, Suffolk. In compliance with the vote of the Council, passed at the October meeting, the committee had given consideration to a complaint against Dr De Cesare, of Lawrence, for bringing suit against an officer and a fellow of the Society. Dr De Cesare had presented an apology, which was published in the *New England Journal of Medicine*, and an admonition was administered by the President. The committee reported that the case was closed. This recommendation of the committee was adopted by vote. Dr Cheever next presented a communication designed to express the attitude of the Society toward matters of publicity (Appendix No 7). It was voted to accept the report.

State and National Legislation

Dr Charles C Lund, Suffolk, presented the report of the committee. In connection with national affairs, he referred to a resolution introduced by Senator Lewis, of Illinois, in the spring of 1937. In effect this resolution would place all private practitioners of medicine in government employ. In accordance with the action taken by other state societies he then presented a resolution (Appendix No 8). Dr Lund presented a second resolution to be submitted to members of Congress and to the President of the United States (Appendix No 9). This resolution had to do with dangers to public health from poorly regulated manufacture of drugs, foods and cosmetics.

The *Legislative Bulletin* of the Society was presented, and the Council was asked to direct the committee in its attitude toward certain bills. First is the bill requiring annual registration of physicians (House Bill 41). It is felt that the bill is better drawn than previous ones, but the committee was not ready to take the responsibility of approving it. The second is House Bill 456, providing for a state fund to replace the present method of handling remuneration under the workmen's compensation law. The committee was in opposition to the bill but, since there might be members of the Council who felt that the bill

time there was cloudy fluid in the abdominal cavity. The fluid showed colon bacilli on culture. The patient's condition gradually became worse and she died 12 days after admission. Autopsy showed the following: colloid adenocarcinoma of the gall bladder with metastases to mesenteric glands, cholecystoduodenal fistula, intestinal obstruction, gallstone in ileum, ulceration of jejunum and ileum, traumatic, with perforation and pelvic peritonitis, operative wounds from ileostomy and cecostomy, pulmonary embolism and infarction, renal infarction, thrombosis of suprarenal artery, polyposis of colon, arteriosclerosis, coronary and aortic, slight, pleuritis, chronic fibrous, bilateral, obesity.

Case 16 A housewife of 42, who was operated upon by Dr. H. H. Faxon, entered the Baker Memorial Hospital on July 13, 1931, complaining of abdominal pain of 3 days' duration. Three nights before admission she suddenly had cramp-like, severe, non-radiating pain in the midepigastrium associated with nausea and vomiting. The severe pain persisted until entry, being localized a little more toward the umbilicus. Her bowels had moved with the help of saline cathartics until the day of entry. Two enemas on the morning of entrance produced no results. For 3 years she had had intermittent attacks of right upper-quadrant pain, radiating on one occasion to the back and associated with nausea and vomiting, but no jaundice.

Examination showed a rather obese middle-aged woman having attacks of cramp-like lower epigastric pain every 5 minutes which lasted about 1 minute. The abdomen was not distended. There was very slight tenderness in the gall-bladder area. The white blood count was 17,000, the temperature 90°F, the pulse 90 and the respirations 21. As the patient was in fairly good condition, conservative treatment was decided upon. A few hours later she suddenly collapsed and was operated upon immediately.

Laparotomy was performed through a lower abdominal incision. A firm mass was felt in the ileum about 60 cm. from the ileocecal valve, it was round and about the size of a golf ball. The bowel was opened and a gallstone removed. The wound was closed without drainage.

The patient's condition was poor throughout the operation, and in spite of a transfusion she died a few hours following operation. No autopsy was done.

Case 17 A housewife of 78 who was operated upon by Dr. A. W. Allen entered the Baker Memorial Hospital on May 12, 1934. She had been known to have a gall bladder full of stones for about 9 years. Three days before admission she had severe right upper-quadrant discomfort, with radiation to the scapula, lasting for 20 minutes. The morning of entrance she complained of gas pains, which were not relieved by a normal bowel movement. About noon the pain became colicky in character and occurred every 5 minutes, lasting about 15 seconds at each attack. An enema gave no relief and caused no results. Nausea and vomiting continued throughout the day.

Examination showed tenderness on the left side of the abdomen near the umbilicus with slight spasm. The

white blood count was 11,000, the temperature 98°F, the pulse 88 and the respirations 16. Conservative treatment was advised. The day following admission, while in the x-ray department, she became nauseated but did not vomit.

An x-ray film taken 9 months before admission had shown two large gallstones in the right upper quadrant, while one taken on admission showed one gallstone in the gall-bladder area with another lying opposite the left ischial spine. An x-ray film taken 2 days after admission showed a moderately dilated loop of what appeared to be the jejunum extending down to the stone.

Two days after admission a laparotomy was performed through a left paramedian incision. The obstruction was about the size of a plum and was gently moved for 8 cm. in the intestine. The bowel was opened through a longitudinal incision, a gallstone was removed, and the bowel was sutured transversely. The abdomen was closed without drainage. The obstruction apparently occurred at the mid ileum.

Following operation, the patient's temperature rose to 105°F and she showed signs of atelectasis. A transfusion was given, the patient's condition improved, and she was discharged relieved on June 9.

330 Dartmouth Street.

his opinion he considered it his duty to make the nominations. It was moved and seconded to rescind the vote passed by the Council in 1902. The President asked the vice-president, Dr Phippen, to take the chair and the discussion proceeded. Dr Mongan, Middlesex South, quoted from a letter sent to one of the members by the Secretary of the American Medical Association which read as follows:

Delegates of the several states are elected to the House of Delegates by the constituent state medical association in accordance with the specific provisions of the by-laws of those organizations. I think it is quite possible that the actual details of the election of delegates are not altogether similar in the various states, but no one has any voice in the selection of delegates other than the members or proper official bodies of the state associations.

Dr Frothingham asked that the quotation from the letter be published since it appeared to indicate that different states select their delegates in different ways. After more discussion, with numerous Councilors taking part, the motion was lost by a standing vote of 40 favoring and 92 opposed.

The President then resumed the chair. He proceeded to announce nominations and, when an attempt was made to make nominations from the floor, he stated that he could not go against the previous action of the Council and that he did not see how it was possible to have nominations from the floor.

Dr Blaisdell, Middlesex East, appealed from the ruling of the chair. Dr Cheever, Suffolk, pointed out that the regulations and laws, under which the Society is enacted, are the by-laws and that these by-laws were passed in 1934. While admitting that, as a matter of procedure, the privilege had been accorded to the President to make nominations, it did not in the least preclude the right of the Council to make nominations from the floor. Dr Frothingham suggested that, if the procedure had been in error, the Council should correct it but that, until the vote directing the President to make nominations had been rescinded, the Council should adhere to that method. Finally, Dr Blaisdell's appeal from the ruling of the chair was brought up for vote and the Council ruled the chair to be in error.

Dr Joslin, Suffolk, moved and it was seconded that the Council reconsider its previous action relative to the precedent established in 1902. Dr Frothingham once more asked Dr Phippen to the chair. After still further discussion, on standing vote, it was found that 92 had voted to repeal the previous action of the Council in 1902 and 33 voted against such repeal. On resuming the chair Dr Frothingham stated that progress had been made, and that

since he believed that the Council now wanted nominations for delegates to be made from the floor he withdrew the nominations he previously made. There was some objection but he insisted. Nominations then proceeded as follows:

Charles E. Mongan (Middlesex South)
Elmer S. Bagnall (Essex North)
David D. Scannell (Norfolk)
Michael A. Tighe (Middlesex North)
Arthur W. Marsh (Worcester)
John I. B. Vail (Barnstable)
Walter G. Phippen (Essex South)
Dwight O. Hara (Middlesex South)

It was voted that the nominations be closed. It was next voted to proceed to elect by ballot. Drs Blaisdell, Lionberger, Homans and Ellison were appointed as tellers. The chair appointed the secretary, Dr Begg, to act as referee and umpire. The Council adjourned for luncheon from 2.00 to 2.30 p.m.

Upon resumption of the session the President called upon the Secretary to announce the count which was as follows:

Charles E. Mongan	77
Elmer S. Bagnall	62
Arthur W. Marsh	58
David D. Scannell	83
Michael A. Tighe	55
John I. B. Vail	21
Walter G. Phippen	71
Dwight O. Hara	81

It was declared that Drs Scannell, O'Hara, Mongan and Phippen had been elected as delegates. Dr Charles C. Lund nominated the other four men for election as alternates with the understanding that the individual receiving the highest number of votes in this group of four be alternate for the delegate receiving the highest number of votes, and the others to follow in a similar order. Dr Lund's motion was carried and it was declared that Drs Bagnall, Marsh, Tighe and Vail had been selected as alternates.

The Council voted to confirm the nominations of the President and to appoint delegates to the annual meetings of the adjoining New England societies as follows:

Maine Frank W. Snow (Essex North)
William D. Walker (Essex North)
New Hampshire Daniel J. Ellison (Middlesex North)
Henry F. Dearborn (Essex North)
Vermont Thomas F. Corriden (Hampshire)
James W. Bunce (Berkshire)
Rhode Island Marshall N. Fulton (Norfolk)
David D. Pratt (Bristol South)
Connecticut Clarence E. Burt (Bristol South)
Theodore L. Story (Worcester)

would be in the interest of the public, a discussion was requested. The third bill, House Bill 1298, requires the licensing of all hospitals. Some changes had been suggested. The matter was presented to the Council for discussion. House Bill 1409 is an act to regulate the selling of medicines which contain enough poison or deadly drug to kill a person if taken in whole or in part. There seemed to be so many complications which might arise, should such a bill pass, that the committee sought guidance. He then proceeded to discuss other bills which were included in the *Legislative Bulletin*. The Council voted to accept the report of the committee and proceeded to take up the various recommendations for action. It was voted to approve of the resolutions submitted by the committee (Appendices No 8 and 9). It was voted not to support House Bill 41. It was voted to oppose House Bill 456. After considerable discussion of House Bill 1298, the Council voted to oppose the bill as drawn. House Bill 1409 was discussed in considerable detail, and it was finally voted not to favor this bill. Following the disposition of the committee's report, the chairman called attention to the long list of bills on medical matters which were before the Legislature this year. He asked the support of the Society for the committee.

Public Health

Dr Robert B Osgood, Suffolk, presented the report of the committee (Appendix No 10). After some discussion as to the possibility of preserving the anonymity of the physicians giving broadcasts, it was finally voted to accept the report.

Medical Defense

Dr Franklin G Balch, Norfolk, presented the report of the committee (Appendix No 11). The committee raised the question as to whether the Society should continue to offer medical defense for its members since, in the majority of instances, physicians already carry malpractice-defense insurance. The Council voted to accept the report.

Permanent Home

The report of the committee was accepted as presented by the chairman, Dr William H Robey, Suffolk (Appendix No 12). Dr Robey then took occasion to refer to a matter not directly concerned with his report. He stated that the donor of the six hundred dollars would probably like to have his name withheld. Dr Robey felt that the Council would like to know that the giver was Dr Walter P Bowers.

There was a vote of appreciation

REPORTS OF SPECIAL COMMITTEES

Cancer

The report of the committee, as presented by Dr Truesdale, Bristol South, was accepted (Appendix No 13).

Postgraduate Instruction

The report of the committee, as presented by the chairman, Dr Ober, Suffolk, was accepted by vote (Appendix No 14). The recommendation that the committee be continued and directed to co-operate with government agencies in carrying out the present plan of postgraduate instruction was adopted.

Public Relations

The report of the committee was presented by the secretary, Dr Bagnall, Essex North (Appendix No 15). It was voted to accept the report.

Miscellaneous

The committee appointed to consider the boundaries of the district societies reported through its chairman, Dr John M Birnie, Hampden. The report was adopted (Appendix No 16).

The committees previously appointed to consider restoration to the privileges of fellowship recommend such restoration under the usual conditions, except as noted in certain cases (Appendix No 17). The action recommended was approved by the Council.

APPOINTMENT OF NEW COMMITTEES

The Council approved of the appointment of new committees to consider petitions for restoration to the privileges of fellowship (Appendix No 18).

The chair announced the appointment of a committee to co-operate with the advisory committee of the State Commissioner of Health to help determine policies in regard to work on gonorrhea and syphilis. The committee consists of Drs Peer P Johnson, Roy J Ward and Alfred L Duncombe. The Council voted to approve the nominations.

APPOINTMENT OF DELEGATES

The President stated that the next business was the appointment of delegates and alternates to the American Medical Association. After some discussion Dr Frothingham explained that, at the February meeting of the Council in 1902, it was voted that delegates to the House of Delegates of the American Medical Association should be appointed by the Council on nomination of the President. The by-laws do not contain the specific vote passed at that time, but the procedure has always been the same with perhaps one exception when a delegate was nominated from the floor. In

APPENDIX NO. 2

REPORT OF THE AUDITING COMMITTEE

The Auditing Committee has required an audit of the books of the Treasurer by a certified public accountant. The committee reports that the certified public accountant examined the securities in the care of the Treasurer and found such to be correct.

EDMUND H. ROBBINS,
JOHN B. THOMES

Hartshorn and Walter
Certified Public Accountants

Boston

January 26, 1938

The Auditing Committee

Dr. Edmund H. Robbins and Dr. John B. Thomes
The Massachusetts Medical Society
Boston, Massachusetts

Gentlemen

At the request of your treasurer, Dr. Charles S. Butler, we have examined the books and accounts of the Massachusetts Medical Society for the twelve months ended December 31, 1937, and submit herewith

Schedule A Statement showing the balance sheet of the Massachusetts Medical Society, December 31, 1937

Schedule B Statement showing the revenue and expenses of the Massachusetts Medical Society for the twelve months ended December 31, 1937

The cash on deposit in the banks has been reconciled with the bank statements and found correct.

The cash receipts as recorded have been properly accounted for and disbursements are supported by vouchers or canceled checks which were examined by us.

The securities and savings bank books in the various funds were examined by us.

The accompanying balance sheet and related statement of revenue and expenses fairly present its position at December 31, 1937, and results of its operations for the year.

Respectfully submitted,
HARTSHORN AND WALTER.

Dr Alexander S Begg was nominated for appointment as delegate to the Annual Congress on Medical Education and Licensure of the American Medical Association to be held at the Palmer House, Chicago, February 14 and 15, 1938. The nomination was confirmed and he was duly elected by vote.

INCIDENTAL BUSINESS

The Secretary presented a list of applicants for fellowship which had been received too late for publication prior to the meeting of the Boards of Censors on November 4, 1937. These individuals were admitted to the examination and were tentatively passed. The Council voted to approve the action taken and to declare these physicians fellows of the Massachusetts Medical Society.

The Secretary presented a change in the by-laws, proposed by Dr Reginald Fitz, chairman of the Committee on Medical Education and Medical Diplomas. This amendment was based upon a resolution adopted at the annual meeting on recommendation of Dr Levi, Middlesex South (Appendix No 19). These changes were presented for information of the Council. The regular procedure for their presentation to the annual meeting will be followed.

The President presented another proposed change in the by-laws designed to divide the work of the Committee on Membership and Finance and to create a new committee which will deal entirely with budget and financial planning (Appendix No 20). Upon being duly moved and seconded it was voted to recommend these changes in the by-laws for adoption by the Society at its annual meeting in June, 1938.

On motion of Dr Walter P Bowers, Worcester, the Council voted as follows:

The Council of the Massachusetts Medical Society, representing over five thousand physicians in the State, in the regular appointed meeting of this second day of February, 1938, hereby records its endorsement of the administration of the Massachusetts Department of Public Health under the direction of the Commissioner of Public Health, Dr Henry D Chadwick. And further that the President and Secretary of the Massachusetts Medical Society are hereby authorized to assure His Excellency, Governor Hurley, that, under the continued service of Dr Chadwick in the position now held by him, the Commonwealth will maintain its generally accorded high standing in the public health administration of the several states of the Union.

The Secretary presented a petition from physicians on Martha's Vineyard requesting that there be established a separate district society on the Island of Martha's Vineyard. The Council voted to refer the communication to Dr Birnie's committee, previously appointed to consider boundaries of district societies.

The Council, after discussion, voted "that a committee of five most recent presidents of the Massachusetts Medical Society be appointed to consider suitable changes in the by-laws which will clarify the method by which delegates to the House of Delegates of the American Medical Association shall be chosen."

Dr Halbert G Stetson, Franklin, reported that he had attended the annual meeting of the Vermont State Medical Society, held in St Johnsbury, Vermont, last fall. It was a two-day meeting, full of enthusiasm and with evidence of hospitality to the delegates. He stated that an excellent program had been prepared.

The Secretary announced that Dr Francis E O'Brien had resigned as secretary of the Hampshire District Medical Society and that Dr Joseph D Collins had been elected to fill the vacancy.

The Council voted to postpone discussion of the subject which has come to be known as "Principles and Proposals."

The meeting adjourned at 3:05 p m.

ALEXANDER S BEGG, *Secretary*

APPENDIX NO 3

REPORT OF THE TREASURER

The past year, 1937, has been a year of advance for the Society in financial affairs. But there have been problems to meet, and the Treasurer has had one problem, in particular that of investing available funds. Interest rates have continued low, offerings of high grade securities, fitted for funds of the Society, have commanded such high prices and yielded such low income returns (as less than 3 per cent for long term bonds), that the Treasurer thought it advisable, from time to time, to buy short-term paper, to carry along, until the future seemed more certain. This practice has, of course, reduced somewhat the income but has protected the principal of the Society's funds.

The Treasurer would again state his opinion, covering the policy of investment to be followed. Because funds of the Society are, in his opinion, funds IN TRUST, they should be invested with consideration, first, of safety of principal. They should not be put in common stocks, which fluctuate widely. It is unnecessary to recall to mind what happened to common stocks in 1929 to 1932, nor to point to the last four months of 1937, when most common stocks, even the best, dropped 40 per cent in price, and many others, dropped from 50 to 70 per cent. For this Society, the Treasurer believes that a moderate, dependable income, with reasonable safety of principal, is the wiser course.

The revenues, in 1937, from annual resident dues, amounted to \$47,754, the largest amount ever received from this source. Nonresident dues amounted to \$1,434 additional, so that the total received was \$49,188.

Income received from invested funds of \$3,965.24 from sales \$62.64, and profit \$149.50—together \$4,177 18—make a combined revenue of \$53,365.20 an increase over 1936, and the largest total annual revenues ever received by the Society.

The Building Fund has been increased by two items first, an annual return of \$1,710 from investments, and secondly, a very generous gift, from Dr. Walter P. Bowers, of \$600. You can probably realize the thrill experienced by the Treasurer when this gift was received. It is a wonderful example of devotion and loyalty to the Society.

APPENDIX NO 6

REPORT OF THE COMMITTEE OF ARRANGEMENTS

The 1938 annual meeting will be held May 31, June 1 and 2, at the Hotel Bradford in Boston. The second day, June 1, will be given over to a combined clinical meeting along the lines of the one which proved so successful last year. Every effort is being made to secure outstanding speakers for this program and to offer to members a morning and afternoon of unusual interest. The various section meetings will be held on the first and third days.

Through planned economy in recent years, the Committee of Arrangements has been able to run the annual meetings at a nominal cost to the Society. This year, we are asking for an appropriation of only one thousand dollars in contrast to twice that amount appropriated by the Council in the past few years.

WALTER S. BURRAGE *Chairman*

Total expenses, during 1937, have increased over \$2000. The expense of publishing an annual directory, a practice begun in 1911, has increased over 1936. The expense to the Society of the *New England Journal of Medicine*, as was expected from the Treasurer's report for 1936, shows an increase, and other expense accounts show increases. Expenses of the Committee on Public Relations also shows considerable increase over 1936. In connection with expenses, the Treasurer urges more careful conformity to budget allotments. The Society has a yearly budget, and the budget should be considered, and not overspent.

A pleasant result of 1937 is that of the Committee of Arrangements. The Council, in 1937, appropriated \$2000 to cover necessary or unforeseen demands for expenses of the annual meeting. With careful supervision of expenses, and larger revenue from commercial booths, this committee turned over to the Treasurer a balance of \$119.33. It is the first time, the Treasurer believes, this result has been accomplished, and shows good management. The Treasurer appreciates the co-operation of that committee, under the guidance of Dr. Rogers.

The Society ended 1937 with unexpended revenue of \$3,902.44. Total assets of the Society now amount to \$181,158, an increase for the year of over \$6,000.

The Treasurer takes this opportunity to thank the officers of the Society and the district officers for their co-operation, and especially thanks the staff of the *New England Journal of Medicine*.

CHARLES S. BUTLER, *Treasurer*

APPENDIX NO 6

REPORT OF THE COMMITTEE OF ARRANGEMENTS

The 1938 annual meeting will be held May 31, June 1
 and 2, at the Hotel Bradford in Boston. The second day,
 June 1, will be given over to a combined clinical meeting
 along the lines of the one which proved so successful
 last year. Every effort is being made to secure outstand
 ing speakers for this program and to offer to members a
 morning and afternoon of unusual interest. The various
 section meetings will be held on the first and third days.

Through planned economy in recent years, the Com
 mittee of Arrangements has been able to run the annual
 meetings at a nominal cost to the Society. This year, we
 are asking for an appropriation of only one thousand dol
 lars in contrast to twice that amount appropriated by the
 Council in the past few years.

WALTER S BURRAGE *Chairman*

APPENDIX NO 7

GENERAL PRINCIPLES GOVERNING PUBLICITY

The distinction between medicine as a liberal, scientific, altruistic profession, and vocations based on industry and commerce has always been jealously maintained by physicians. In this connection, advertising—one of the chief foundations of competitive business—is not employed by physicians, since it tends to lower the dignity of the profession and to give a false idea of values and thus impairs the usefulness of the profession to the public. In the past, the sole approved way for physicians to make themselves and their qualifications known was by joining medical societies and taking part in their activities, writing for medical journals, and establishing a reputation which spread in a natural way among the laity. They were denied the usual avenues of publicity open to business men.

These principles are as sound today as ever before. New conditions affecting all mankind, especially the vast development of more effective means of communication by press, radio and film, and new concepts of the desirability of informing and educating the public on matters formerly considered to lie within the sphere of interest of a small class only, are profoundly affecting the status of the physician, with the result that he must participate in these activities. Such participation is fraught with the possibilities of abuse which may harm the profession. Publicity and educational propaganda actively carried on by physicians must be regulated with care by organized medicine. The following code is suggested for adoption by the Massachusetts Medical Society for the guidance of its fellows, officers and standing committees to enable them to protect its standards.

As a preamble it may be stated that now as always, the best way to impress the public with the value of scientific medicine is for every practitioner to make himself competent, conscientious and sympathetic in carrying out his professional duties. If every layman could have frequent personal relations with such a physician most of the problems concerning the medical care and education of the public would cease to exist.

Every form of publicity and propaganda in which physicians engage must have for its sole object the benefit of the public through education. If its effect is to aggrandize and advertise the merits of an individual physician or group of physicians, it is objectionable and contrary to the spirit of the Code of Ethics of the Massachusetts Medical Society. If such aggrandizement and advertisement are inevitable and unavoidable incidents in securing an important educational advantage to the public, they should be reduced to an absolute minimum and the burden of proof that they are in fact necessary must rest on the physician involved.

Educational propaganda should be, if possible, under the name of a physician who is not engaged in active private practice in competition with his fellows. Thus officials of boards of health, full time teachers in medical schools or duly appointed committees of the Society or of its component district societies constitute the most appropriate agents, who are understood to be acting under the aegis of such institutions. Certain institutions such as hospitals which function as community health centers not conducted for profit, or bona fide educational organizations not conducted for profit, may sponsor propaganda, but physicians who act for them should conform to the above types.

It is recognized that under certain circumstances, which

it is believed will be exceptional, a physician engaged in private practice may be the most available person to convey necessary or useful information to the public. If so, it is highly desirable that the subject covered in his address or paper should not be identical with his own field of practice. If such identity cannot be avoided, it is essential that no reference be made to his own experience, accomplishments or peculiar abilities, to the number of his patients or the success of his treatment. The pronouns of the first person—"I," "me," "my," "we," "us," and "our"—should be conspicuous by their absence. Introductions of a speaker on the radio or platform should consist merely of his name, if that be required, and only such additional words as are necessary to identify him. All laudatory comments on him or his work should be avoided or reduced to a minimum. Observance of the canons of good taste will be most helpful to the reputation of the profession.

The acceptance by a practicing physician of employment by a commercial organization to give a radio address, even though it be on public health matters rather than on the merits of the product manufactured or distributed by the concern, is not permissible. Such an association between physician and business cannot fail to cause one to be identified with the other, and to make the public believe that the physician and therefore his profession endorse the product. Such an activity cannot be considered as bona fide altruistic education of the public.

The petty publicity conferred by the daily press on certain physicians—mention of their activities, of their prominent patients and their progress, of their acquisition of new apparatus and kindred bits of news—constitutes an advertisement—usually unsought but sometimes not discouraged by the victims. It is recognized that the intensive news gathering and lack of respect for personal privacy which characterize the modern era make some of this publicity practically unavoidable, but the physician who abhors it and meets its temptations with dignity and firmness is not likely to be subject to the criticism of his fellows on the score of advertising.

All communications by private physicians—on the air or platform or in the lay press—which could possibly be regarded as of doubtful propriety on the ground of unethical publicity should be submitted for approval before hand to the appropriate officers of the Massachusetts Medical Society.

In formulating, for the guidance of our fellows, this code of behavior, it is the intention of this committee that our Society maintain the essentials of those traditional concepts of behavior which should be fundamental and unchanging, and at the same time recognize the changed and still changing conditions of modern life and encourage wise and reasonable adjustments to them. It is believed that an attitude which promotes the reputation of the physician as a high minded, unselfish humanitarian ensures the best service to the public.

APPENDIX NO 8

RESOLUTION ON FEDERALIZATION OF MEDICAL PROFESSION

WHEREAS, Senate Joint Resolution 188, introduced on July 28, 1937, in the Senate of the United States by Senator J. Hamilton Lewis, of Illinois, proposes to federalize the medical profession of the nation, making every licensed physician and surgeon a civil officer and subject to prose

cution and penalization in the federal courts for special causes enumerated in the resolution, and

WHEREAS Such action being clearly a case of class legislation is contrary to the principles of constitutional government, and

WHEREAS, The obligation imposed by the Joint Resolution upon each licensed physician of rendering needed medical service to any and all impoverished who make application to him would inevitably overwhelm practitioners of outstanding reputation, create the necessity of elaborate machinery to determine who would qualify as impoverished or in lieu thereof open the way for fraudulent practices, political interference and tend to lower the standards of medical practice, and

WHEREAS, The authority reposed by the Joint Resolution in the Social Security Board would lead almost certainly to fee fixing by governmental agencies and would necessitate a nation wide accounting and investigating system that would add a tremendous indirect cost to the nation's bill for medical care and

WHEREAS, The penalties imposed by the Joint Resolution on persons who violate the provisions thereof are so exorbitantly severe as to create a detrimental and inimical psychology in the medical profession, and

WHEREAS, The proposed plan would lend itself easily to political abuse and become a stepping stone to communistic and socialistic government, and

WHEREAS, Poverty itself is the fundamental cause of most of the ills which the Joint Resolution seeks to cure and prevent through the superficiality of a superimposed medical service, and

WHEREAS, The enforcement of local laws already on the statute books would provide as adequately for the sick poor as modern facilities and circumstances make practicable, and

WHEREAS, The needy now enjoy as adequate medical care as economic limitations and the vagaries of human nature would make possible under the proposed plan therefore, be it

RESOLVED BY THE COUNCIL OF THE MASSACHUSETTS MEDICAL SOCIETY IN REGULAR SESSION ASSEMBLED, That Senate Joint Resolution 188 is inimical to the best public interests, is un-American and unworkable, would result in monumental expenses without yielding compensating benefits, would lead to political corruption and tyranny and ought to be defeated, and, be it further

RESOLVED, That copies of these resolutions be forwarded to the President of the United States, to each senator and representative in Congress from Massachusetts and to the secretaries of the medical societies of the several states

APPENDIX NO 9

RESOLUTION ON FOODS, DRUGS AND COSMETICS

WHEREAS, The existing federal laws and regulations governing the manufacture and sale of drugs, foods and cosmetics are insufficient to protect the public from serious harm and even death, and

WHEREAS, The recent investigations of the United States Department of Agriculture show conclusively the need for further and more stringent action therefore be it

RESOLVED, That the Massachusetts Medical Society through its Council urgently petitions the President of the United States and Congress in support of such legislation and respectfully urges that the enforcement of the laws and

the regulations issued under such authority should be vested in the Division of Food and Drugs Administration in the Department of Agriculture.

RESOLVED, That copies of these resolutions be forwarded to the President of the United States, to each senator and representative in Congress from Massachusetts and to the secretaries of the medical societies of the several states.

APPENDIX NO 10

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

The Committee on Public Health and the Subcommittee on Public Education beg leave to submit the following report

The Committee on Public Health has succeeded in obtaining the co-operation of the Massachusetts Central Health Council in helping to carry out the vote of the Council passed at its meeting in April, 1935, to encourage the formation of community health centers in various districts throughout the State under the initiative of the different district societies wherever the provision for more adequate medical care seems to be desirable and likely to be favored by such action.

The Massachusetts Central Health Council is a voluntary association of sixteen existing private and public agencies concerned directly or indirectly with health. Its purpose is to co-ordinate these activities, thereby eliminating duplication of effort and increasing efficiency.

At a meeting of the Central Health Council held on December 3, 1937, on motion of Dr. Richard M. Smith, one of the representatives of the Massachusetts Medical Society on the Central Health Council, it was voted to appoint a committee to meet with representatives of the Committee on Public Relations of the Massachusetts Medical Society to discuss with them the ways and means by which the Massachusetts Central Health Council might be of service in the establishment and conduct of any such community health centers. This committee of the Massachusetts Central Health Council was given power to act for the Council. There is no suggestion that such co-operation involves any measure of control of these district health centers, which in the opinion of the Committee on Public Health, should be both initiated and managed by representatives of the district societies. The committee urges the district societies to explore the need for a community health center in their own localities and to familiarize themselves with the investigations of Dr. Ernest L. Hunt in the Worcester district and with the plan which he and his co-workers have proposed to meet the demonstrated need in their district. The Public Relations Committee voted on June 2, 1937, to invite the Worcester District Medical Society to proceed with the establishment of such a community health center.

The activities of the Subcommittee on Public Education have centered about the radio broadcasts sponsored by the Massachusetts Medical Society and the State Department of Public Health.

The committee hopes that the fellows of the society are listening in to these broadcasts on Wednesday evenings at 7.30 over Station WAAB. Thus far, with the exception of less than a dozen addressed postal cards asking for comments and suggestions, fifty of which were distributed at the last meeting of the Council to fellows who expressed willingness to listen in and mail their suggestions, no comments have been received by the secretary of the subcommittee, Dr. Gerald N. Hoeftel, 319 Longwood Avenue, Boston. A very considerable and gratifying amount of fan mail asking for copies of the differ-

ent broadcasts has been received, which suggests that the public are finding these broadcasts interesting and helpful. Through the co-operation of the State Department of Public Health, it has been possible to mail mimeographed copies of the desired broadcasts to all who have asked for them. With this co-operation of the State Department of Public Health only a minimum expense to the Society has been incurred.

The Subcommittee on Public Education takes this opportunity of warmly thanking the eminent fellows of the society who have given their time and thought to the preparation of these broadcasts and have been so willing to accept the suggestions of the subcommittee as to the content and form of presentation of these broadcasts. The committee also expresses its gratitude to the *New England Journal of Medicine* which receives copies of all broadcasts for the publication of those which in the opinion of the editorial board are of value to the profession.

The committee has been asked for its opinion upon a matter which seems to it to be of considerable importance. A fellow of the society who had been broadcasting on medical subjects under his own name for a non-medical educational institution sought the advice of the officers of the society as to the ethics of the procedure. The matter was referred to the Subcommittee on Public Education, which interviewed said fellow, reviewed several broadcasts that he had already delivered and was proposing to deliver. The material for the most part was innocuous and contained little which could be construed as self-advertisement. Nevertheless, realizing that the practice involved a matter of principle, he was advised to desist from further broadcasting of this kind at least until an opinion from the Committee on Ethics and Discipline could be obtained. This he agreed to do. The whole matter was then referred to the Committee on Ethics and Discipline for complete review.

The New York Academy of Medicine and the New York County Medical Society have been faced by similar situations and after careful consideration have published a brochure entitled, "Principles Governing Contact of Physicians with the Public Through the Press, Lecture Platform, Lay Periodicals and Radio, by which medical men in that locality have been made aware of the opinion of the Academy and the County Society as to the ethics of public medical education in relation to addresses and broadcasts. It seems to be a most useful guide.

The Subcommittee on Public Education has been informed that the Committee on Ethics and Discipline has undertaken the task of drawing up such a guide for the Massachusetts Medical Society, copies of which are to be sent to each member of the Society for comment. It is expected that the final recommendations of the Committee on Ethics and Discipline will be presented for action by the Council at the next annual meeting.

ROBERT B OSGOOD *Chairman*
GERALD N HOEFFEL *Secretary*

APPENDIX NO 11

REPORT OF THE COMMITTEE ON MEDICAL DEFENSE

Though the Committee on Medical Defense has no definite report to make at this meeting, I do want to say a few words on the general subject of defense of malpractice suits.

We have requests on the average of three a year, and I find that our expenses are running close to the two-thousand-dollar limit. Rarely one of these men sued has never thought it necessary, on account of the practice he

was in, to carry any kind of insurance, such men include those in state positions, house officers, and so forth. These men I think we should defend but it worries me to carry some of the cases which apply for help. They seem to me an unnecessary tax upon the more provident members of the Society who carry their own insurance.

Insurance now costs little and malpractice defense does not seem to me a necessary duty of the Society except in certain cases. The committee should be kept in existence and perhaps take care of the defense of members for good reason only on a vote of the whole committee instead of just the chairman and secretary.

When the committee was founded, it was expected that it would carry out various functions which it never has. It was supposed to prevent suits by going to the parties and talking to each side. Under the old Medical Defense Act it said "It shall study and report upon the underlying causes of the growth in the number of suits for malpractice, and it shall exert, so far as possible, its influence to check this growth. In specific instances it shall take counsel with both plaintiff and defendant in threatened suits. It shall report to the Committee on Ethics and Discipline any instance coming to its knowledge wherein a fellow, in connection with a suit for malpractice, has violated the Code of Ethics of the Society." * * * * I consulted with one of the most prominent judges of the superior court in Massachusetts who informed me that I should find myself in trouble very promptly if I tried to prevent men from testifying or in other ways interfered with the carrying out of the law. Consequently, that section had to be dropped. I have personally always felt that a man had a right to testify either for the plaintiff or defendant and that if he told the truth, it was none of our business whether he testified. Where complaints have been brought about testimony given by doctors in court, I have if possible obtained a transcript of the testimony. Unfortunately, the worst evidence that has been given has been given by out-of-state men, and we have no way of controlling them. I have taken it up in some instances with the secretaries of the state societies, but they have not been particularly co-operative. I think the knowledge that their testimony would be examined has had the effect of making some rather flagrant offenders careful in the way they testify, and for the last few years I have had no complaints about unfair testimony.

I believe that the fact that the Society pays no verdicts even if one is given against a doctor tends to lessen the number of suits very materially, and to that extent it certainly is useful. Of course the policies in the various commercial companies read in these days that the company shall not compromise a suit except with the written permission of the defendant. Doctors hate being sued and will do anything to get a case finished up. They are therefore not very loath to let a company settle a suit since they themselves do not have to pay for it and can thereby get the trouble off their minds. I am perfectly convinced that if every suit were fought, it would reduce litigation very materially. Again, if the doctor himself in every case had to pay the verdict, patients would often be very slow about suing.

Taking it altogether, I think the Society's defense of suits has certain very worth while aspects for both those who are sued and those who are not. On the other hand it seems very expensive and perhaps some way could be devised to reduce the costs. The one thing we certainly do not want to do is to employ any second rate lawyers. In all the time I have been connected with the committee, Mr. Dodge's firm has won, or had put aside, all but two suits. In one of these we were beaten before we started

and had advised the man to compromise. He had no money to do it. In another suit we lost because the doctor became very apprehensive and said he wanted the suit settled at any cost. Under the new Medical Defense Act, we can no longer tell a doctor whom he shall employ to defend him if we are to pay for the suit, and I think this may lead to complications. Perhaps by the June meeting we will have some definite recommendations to make as to whether the Society should continue to insure its members. I am gradually becoming convinced that that is not a necessary function of the Society.

FRANKLIN G. BALCH, *Chairman*

APPENDIX NO 12

REPORT OF THE COMMITTEE ON PERMANENT HOME

The Building Fund of the Massachusetts Medical Society, which is managed by the Committee on Permanent Home, showed on December 31, 1936, a book value of \$57,951.07 compared with the present book value of \$60,261.40, an increase of \$2,310.32 for the year 1937. The income from the Fund in 1937 came from two sources: (1) interest from investments of \$1,710.32 and (2) a gift of \$600 from Dr. Walter P. Bowers. There is also a note of \$20,000 unsecured with interest at 4½ per cent, of the Boston Medical Library but this note has not been reduced by any payment on principal in 1937.

I have had several conferences with Dr. Butler, our treasurer, who has given me the figures already stated. I have not called a meeting of our committee because it appears that while we might buy a suitable piece of property, at the present time none is located in a desirable part of the city for our purposes. Again, if we bought such a building we would have to make certain structural changes and would also be put to the expense of furnishing the house all of which would mean considerable outlay, probably more money than we can afford to spend at present, so it seems as though it would be well for us to mark time.

WILLIAM H. ROBES, *Chairman*

APPENDIX NO 13

REPORT OF THE COMMITTEE ON CANCER

During the past months, the objectives of the Women's Field Army of the American Society for the Control of Cancer have been discussed from various angles. It was felt advisable that the Women's Field Army put on no drive in Massachusetts during 1938 owing to the conflict of their plans with the Massachusetts program. This was agreed to by Dr. Little as Executive Director of the American Society for the Control of Cancer.

It is obvious that the American Society for the Control of Cancer has little conception of the extensive program of lay education being carried on in this state under the joint auspices of the Massachusetts Medical Society and the Massachusetts Department of Public Health. There are at the present time co-operative cancer control clinics formed in two thirds of the towns and cities of the Commonwealth. Each consists of one representative from each organization, social or fraternal, in the town, and the total membership of these committees is over 5200. Each committee member arranges an address on cancer before his own organization at least once during the year. Emphasis has been laid on those talks being given by

physicians in the community. In this way, approximately 100,000 persons should be given information about cancer during the coming year, largely through their local general practitioners.

Since the *Commonwealth* number on 'Cancer' has been exhausted and requests for it are continually coming in (over 5000 copies have been distributed), it has seemed advisable to request the American Society for the Control of Cancer to allocate funds obtained in the Massachusetts drive of the Women's Field Army last year for the purpose of reprinting an enlarged and revised cancer booklet for distribution to those physicians interested in cancer control and education. We desire to make available to every physician in the Commonwealth such recent and authoritative information on cancer as he may require in discussion of the subject with his fellow practitioners and with the public.

It must be recognized that any campaign for education of the public with regard to cancer must rest on the initiative, knowledge, and missionary spirit of practitioners of medicine, because it is our conviction that any attempt at lay education by laymen will inevitably lead to misunderstanding and misinformation.

SHIELDS WARREN, *Chairman*

APPENDIX NO 14

REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

Last winter the general committee recommended that, after February 1, 1937, the Executive Committee cease active operations pending the result of negotiations with the state and federal agencies in regard to curricula and finances. Last June the committee recommended to the Council the following budget:

Massachusetts Medical Society	\$1000.00
State and federal agencies	4279.84
Total	\$5279.84

This recommendation was approved by the Council on June 2, 1937.

During last summer the Executive Committee negotiated with Dr. Chadwick, State Commissioner of Health, in early September, 1937, approval of the program and budget was secured from the United States Public Health Service, the Federal Children's Bureau and the State Department of Public Health.

During 1937 the committee had an appropriation of \$1000, of this amount \$766.67 was used, and the residue reverted to the treasury. The Executive Committee has requested an appropriation of \$1000 for 1938 to carry on the activities of the committee.

The Executive Committee organized a curriculum and began instruction on January 6, 1938. At the present time, courses are in progress in the following districts: Bristol North (Taunton), Bristol South (New Bedford), Essex South (Salem), Middlesex East (Melrose), Middlesex North (Lowell), Norfolk (Norwood), Norfolk South (Quincy), Plymouth (Brockton), Worcester (Milford) and Worcester North (Fitchburg).

In the spring the courses will be given in the following districts: Barnstable (Hyannis), Berkshire (Pittsfield), Bristol South (Fall River), Franklin (Greenfield), Hampden (Holyoke and Springfield), Hampshire (Northampton) and Middlesex South (Cambridge).

The committee wishes to report that there has been a most cordial spirit of co-operation between the gov-

ernment agencies and the committee. So far, comments from the districts have been generally favorable in regard to the courses. The chief change in the teaching has been the introduction of clinical demonstrations which have been well received. The courses have been offered free of charge to all legally registered doctors in the respective district societies.

It is recommended that the committee be continued and directed to co-operate with the government agencies in carrying out the present plan of postgraduate instruction.

FRANK R. OBER, *Chairman*
LEROY E. PARKINS, *Secretary*

APPENDIX NO 15

REPORT OF COMMITTEE ON PUBLIC RELATIONS

Landesman Resolution

Resolved, That a committee of five be appointed by the President of the Massachusetts Medical Society for the purpose of ascertaining what the actual duties are of the city and state health departments according to statutes, in order to prevent officers of these departments from encroaching upon, usurping legitimate practice, and undertaking unfair competition with the medical profession.

WILLIAM G. CURTIS, *Chairman*,
FRANCIS P. MCCARTHY,
HENRY M. LANDESMAN, *Secretary*

Discussion revealed that this matter had been considered in the report of this committee to the Council in June, 1935.

Lane Resolution

WHEREAS, The Massachusetts prepaid hospital plan has been endorsed in principle only by the Massachusetts Medical Society, June 9, 1936, and

WHEREAS, In numerous sections of the country similar plans have been on trial with varying degrees of success, and

WHEREAS, It is apparent that a definite line of demarcation must be drawn between the fundamental principles of medical practice and hospital services, and this distinction must be rigidly followed to insure success, and

WHEREAS, We, the Council of the Massachusetts Medical Society, being deeply concerned with preserving the best interests of patients, physicians and hospitals, as is the Associated Hospital Service Corporation, desire to maintain basic principles of medical practice and high standards of ethics to obtain the best results, therefore be it

RESOLVED, That we approve the prepaid hospital plan, with the stipulation that the contract benefit provided by group hospitalization insurance shall be limited to hospital accommodations such as room, bed, board, operating room facilities and general nursing care ordinarily provided by hospitals, routine drugs, and the routine service of interns only when acting under the direction of the attending physician, and that except as stated above, the contract shall not include the services of physicians either general or special. The term *physician* as used here shall be understood to include all licensed practitioners holding the degree of Doctor of Medicine, who assume on their own account to interpret laboratory and x-ray findings in terms of disease and diagnosis, or to administer or direct treatment.

Dr. Lane accepted the following amendment to his resolution

except as this resolution affects contracts now existing between hospitals and pathologists

The committee voted without dissent to postpone consideration and modification of the Lane Resolution until such time as the position of the pathologists on the matter can be determined. (Representative pathologists indicate that they have not yet crystallized sentiment in their specialty regarding their relation to prepayment hospital contracts but expect discussion at a forthcoming meeting.)

District Health Councils

The committee has again attempted to stimulate activity on the Hunt Plan for district health councils. This Council endorsed the plan and urged its initiation by district societies at the annual meeting in June, 1936.

The Board of Trustees of the American Medical Association at a meeting late in December, 1937, adopted the following resolutions which embody the spirit of the Hunt Plan.

WHEREAS, A varying number of people may at times be insufficiently supplied with needed medical service for the maintenance of health and the prevention of disease, and

WHEREAS, The means of supplying medical service differ in various communities, be it

RESOLVED, That the American Medical Association summarize the state and county medical societies to assume leadership, securing co-operation of state and local health agencies, hospital authorities, the dental, nursing and correlated professions, welfare agencies and community chests in determining for each county in the United States the prevailing need for medical and preventive medical service where such may be insufficient or unavailable and that such state and county medical societies develop for each county the preferable procedure for supplying these several needs, utilizing to the fullest extent medical and health agencies now available, in accordance with the established policies of the American Medical Association. Be it further

RESOLVED That the Board of Trustees of the American Medical Association establish a committee to co-operate with the Bureau of Medical Economics in outlining the necessary procedures for making further studies and reports of the prevailing need for medical and preventive medical services, and that the Secretary of the American Medical Association arrange to develop such activities through the secretaries of state and county medical societies in each instance, urging the formation of special committees in each county and state where committees are not available for this purpose.

Your committee voted to sponsor a joint meeting of all members of public relations committees of the several districts to promote the spirit of the plan and secure its adoption in whatever form is best suited to their respective communities.

ELMER S. BIGNALL, *Secretary*

APPENDIX NO 16

REPORT OF COMMITTEE TO STUDY THE BOUNDARIES OF THE DISTRICT SOCIETIES

At the 1937 February meeting of the Council a committee of five was authorized whose duty it would be to study the matter of boundaries of the district societies of the Massachusetts Medical Society.

This committee felt that as a result of the excessive use of transfer privileges certain district societies have accumulated a membership list which is unwieldy and serves neither the best interests of its members, the State Society, or the people. It would seem that any district society whose membership exceeds 300 is unwieldy and the parent body should consider favorably an application for partition on the part of a representative group within the district, capable of establishing and developing a new district society either by its own membership or in conjunction with a similar group split off from a neighboring district.

In order to ascertain whether the committee was justified in the foregoing opinions the chairman wrote to the secretary of each district society asking if any changes in district boundaries seemed advisable or desirable. Only eight secretaries of the eighteen districts replied to these inquiries. These eight secretaries stated that their districts were satisfied with their existing boundaries.

The first few lines of Article VII of the constitution of the Massachusetts Medical Society read as follows: The Councilors, upon the application of any five members of the said Society, may establish within such districts and portions of this Commonwealth as they shall think expedient, subordinate Societies.'

Inasmuch as there seems to be no interest on the part of the district societies in revising the existing district boundaries, and as the constitution of the Society already provides the means of forming new district societies, your committee makes no recommendation.

JOHN M. BIRNIE, *Chairman*

APPENDIX NO. 17

REPORTS OF COMMITTEES APPOINTED TO CONSIDER RESTORATION TO THE PRIVILEGES OF FELLOWSHIP

- 1 For Maxwell H. Bloomberg, Boston (Committee Andrew R. MacAusland, Archibald M. Fraser and Harold G. Lee)
- 2 For Chester P. Brown, Swampscott (Committee Loring Grimes, Hamlin P. Bennett and Mason R. Pratt)
- 3 For Alice E. Butler, Boston (Committee Eleanor B. Ferguson, Louisa Paine Tingley and Letitia D. Adams) This committee recommended that her past dues be remitted and that she pay dues for the current year.
- 4 For William A. Hunter, East Gardner (Committee Albert F. Lowell, Charles E. Thompson and Paul E. Dunn)
- 5 For Joseph Lentune, Boston (Committee Harlan F. Newton, Wyman Richardson and Laurence B. Ellis)
- 6 For Maurice Lugitch, Dorchester (Committee Hyman Morrison, John B. Hall and John P. Powers)
- 7 For Joseph E. Marien, Fitchburg (Committee George P. Norton, Thomas R. Donovan and Antonio D. Delisle)
- 8 For James H. Mason, Worcester (Committee George E. Emery, George A. Dix and George C. Lincoln)
- 9 For Arthur J. Tavera, New Bedford (Committee Thomas B. Horan, Wilford J. Rousseau and Carl C. Persons)
- 10 For Raymond C. Whitney, New Bedford (Committee Aubrey J. Pothier, Augustus H. Mandell and Harold E. Perry)

- 11 For Angelo M. Zarrella, Lynn (Committee Charles L. Hoyt, Charles A. Worthen and Frank E. Stone)
- 12 For T. N. Zervas, Lynn (Committee Nathaniel P. Breed, Stephen R. Davis and John W. Trask)

APPENDIX NO. 18

COMMITTEE APPOINTED TO CONSIDER PETITIONS FOR RESTORATION TO FELLOWSHIP

- 1 For J. B. Bakst, Lynn
Frank E. Stone, John W. Trask and Saul M. Marcus.
- 2 For Frederick W. Celce, Holyoke
Edward P. Bagg, Jr., Fred H. Allen and Philip H. Clarke.
- 3 For Abraham Green, Brookline
Charles J. Kichham, Albert Ehrenfried and John A. Seth.
- 4 For Aaron Kaufman, Boston
Joseph J. Skarball, Allen P. Joslin and Maurice B. Strauss.
- 5 For Raoul J. LeBeau, Spencer
James C. Austin, John R. Fowler and Alfred W. Brown.
- 6 For Joseph H. McLaughlin, Dorchester
Henry F. R. Watts, Carlton E. Allard and William J. Walton.
- 7 For Edward C. Messer, Dorchester
David G. Eldridge, Samuel Nadel and John B. Hall.
- 8 For Morris J. Ritchie, Westfield
Archibald J. Douglas, Edward S. Smith and Robert M. Marr.

APPENDIX NO. 19

A PROPOSED CHANGE IN CHAPTER I, SECTION I OF THE BY LAWS

Dr. A. S. Begg,
Massachusetts Medical Society,
Boston, Mass.

Dear Dr. Begg:

It seems to me that when the Council passed Dr. Levi's resolution on June 2,

RESOLVED That the names and addresses of applicants for membership in the Massachusetts Medical Society and the name and address of the secretary of the district be published together in a special list in the *New England Journal of Medicine* at least two weeks prior to each censors meeting,

they really made a change in the by laws. I would suggest, therefore, that the following resolution be brought up

WHEREAS, On June 2, 1937, the Council passed a resolution presented by Dr. Alexander A. Levi to

the effect that the names and addresses of applicants for membership in the Massachusetts Medical Society and the name and address of the secretary of the district henceforward should be published together at least two weeks prior to each censors' meeting, and

WHEREAS, By passing this resolution the Council in effect made a change in the by laws directly modifying Section 1 of Chapter I dealing with requirements for fellowship, therefore be it

RESOLVED, That Chapter I, Section 1, of the by laws of the Society be amended to read as follows

Section 1 Applicants for admission to fellowship in the Massachusetts Medical Society are required to satisfy the censors that they are not less than twenty-one years of age, that they are of sound mind and of good moral character, that they possess a good English education, that their names and addresses and the name and address of the secretary of the district society in which they reside have been published in a special list in the *New England Journal of Medicine* at least two weeks prior to their examination by the censors, that they have received a diploma from a medical school or college recognized by the Council, or that they have, in each instance, received the approval of the Committee on Medical Education and Medical Diplomas, that they do not practice medicine in a manner contrary to the Code of Ethics of this Society, and they shall appear personally before the censors and satisfy them that the above requirements are fulfilled.

Yours sincerely,

REGINALD FITZ, M.D.

APPENDIX NO 20

PROPOSED CHANGES IN THE BY LAWS

The following paragraphs in the designated chapters under the proposed changes will read as follows

CHANGE NO 1 (Appendix 19)

CHANGE NO 2

CHAPTER VI (DUTIES OF TREASURER)

Section 4

Paragraph 4 He shall attend the meetings of the Committee on Financial Planning and Budget, furnish the committee with such data as it may require and shall make all investments and reinvestments of the Society's funds with authority to buy or sell securities subject to the approval of this committee.

CHANGE NO 3

CHAPTER VII

Section 3

The Committee on Membership shall consist of five fellows. It shall hold a stated meeting the week next preceding each council meeting and such other meetings as may be necessary.

The committee shall consider all matters relating to honorary or associate fellowship, retirement, resignation, deprivation of the privileges of fellowship or remission of dues, and shall make recommendations to the Council concerning the same. It shall consider all petitions of fellows to be transferred from one district society to another in accordance with the provisions of Chapter III, Section 3.

All bills incurred shall be countersigned by the chairman and forwarded to the president for his approval.

CHANGE NO 4

CHAPTER VII

Section 10

The Committee on Financial Planning and Budget shall consist of five fellows. It shall hold a stated meeting during the week before the February meeting of the Council and such other meetings as may be necessary.

It shall consider in a broad way how the Society can best use its income. Based upon such consideration it shall recommend to the Council at its February meeting the budget for the current fiscal year, after consideration of the estimates for expenses for the current fiscal year that have been submitted by individual members, the committees and officers of the Society. It shall consider all requests for extraordinary appropriations and shall recommend to the Council whether or not they shall be granted.

Following the close of each fiscal year, this committee after consultation with the treasurer with the approval of the Council shall determine the amount to be refunded to the several district societies from the balance remaining in the treasury on December thirty first. This amount shall be apportioned among the district societies according to the number of annual assessments which shall have been paid to the district treasurers previous to March first.

All bills incurred shall be countersigned by the chairman and forwarded to the president for his approval.

CHANGE NO 5

CHAPTER VII

Section 11

Reports of standing or other committees containing recommendations which may require mature consideration before their adoption shall be sent in abstract to the secretary of the Society, at least four weeks before their presentation to a meeting of the Council, for publication in the official organ of the Society.

PROGRESS IN TUBERCULOSIS, 1936-1937

JOHN B. HAWES, 2ND, M.D.,* AND MOSES J. STONE, M.D.†

BOSTON

THE advances made in the past decade in the field of pulmonary tuberculosis have been so rapid and so striking that by comparison the past year appears comparatively barren as to new advances or real progress.

Both diagnosis and treatment are now on a concrete basis. Most of the controversial points are rapidly disappearing. The x-ray occupies a pre-eminent place in early diagnosis. Collapse therapy is definitely recognized as the best mode of treatment in the active and advancing types of this disease. Laboratory studies are on a firm footing as adjuvants in diagnosis as well as in treatment. One is no longer satisfied with direct smear examinations of the sputum. In negative cases, the concentration method is being adopted in all the best sanatoriums. In the majority of institutions, the culture method as well as that of guinea pig inoculation is required before one can designate a case of tuberculosis as closed or negative.

The outstanding advances of the past year have been made through epidemiologic studies. Education along every line has accomplished much. The public is becoming more aware of the tuberculosis problem, and is willing to spend money as well as to submit to examinations in order to guard against this disease. The detection of tuberculosis is now an integral part of state and city health departments as well as of community organizations. We are no longer satisfied to wait for patients to come to the doctor's office, but are searching for the disease in the apparently healthy members of the community. While this activity lacks the dramatic element of laboratory and clinical research, it constitutes progress in the right direction.

EPIDEMIOLOGY

Schuman (*Am Rev Tuberc* 34 85-95, 1936) has made a study of contact as a factor in the transmission of tuberculosis. He emphasizes positive sputum as the greatest single factor in the spread of pulmonary tuberculosis. He finds a definite relation between the incidence of tuberculous infection in children and a positive sputum contact. In his investigation, individuals exposed to positive sputum cases showed an increased degree of sensitivity, as is indicated by the intensity of reaction to tuberculin. He points out what was well known before: that control of positive sputum cases is the most effective means of limiting the spread of the disease.

*President Boston Tuberculosis Association.

†Assistant professor in medicine Boston University School of Medicine. Assistant physician Beth Israel Hospital.

Shurly and Brachman (*Am Rev Tuberc* 34 96-106, 1936) remind us of the latent sources of contact, and plead for a more widespread search for tuberculous individuals, particularly where people gather regularly for work, education, recreation or partaking of food.

In a study of tuberculosis in college students, Shepard (*Am J Pub Health* 25 1118-1124, 1935) says that the American Student Health Association calls for surveys, including histories, physical examinations, tuberculin-testing, x-ray studies of positive reactors and the follow-up of cases discovered or suspected. Recent surveys have shown about ten times as many known cases of tuberculosis in colleges with control programs as in colleges with no methods of early detection.

Harrington, Myers and Levine (*J A M A* 104 1869-1874, 1935) write that school surveys should and must include the entire personnel. In a campaign conducted in the Minneapolis schools, definite evidence of parenchymatous involvement was found in 78 teachers or other employees. Of these, 69 apparently had pulmonary tuberculosis and 9 had nontuberculous lesions. One employee was found to be disseminating tubercle bacilli, and 68 others presented lesions that were probably due to tuberculosis of the parenchymatous type. Subsequent examinations have brought to light 5 more open cases of tuberculosis. These writers recommend periodic examinations of those with non-progressive lesions.

The problem of home contacts receives the attention of Kayne (*Brit M J* 1 692-696, 1935). He concludes that postnatal contact is by no means always fatal and does not always infect, but does so in a large proportion of children. He urges early separation of children from the source of contact, though they may already be infected. He feels that such separation is certainly indicated up to the age of five.

Stewart (*Am J Dis Child* 50 853-871, 1935) deals with the relation between the childhood or primary type and the adult or reinfection type of tuberculous disease. His conclusion is that primary infection, aside from the danger of miliary dissemination or meningitis, leads to a change in tissue sensitivity which is distinctly harmful as regards later reinfection. This being the case, he says, a first infection with tubercle bacilli is not necessarily a beneficial protective experience. By his view, tuberculosis can best be prevented by

the effect that the names and addresses of applicants for membership in the Massachusetts Medical Society and the name and address of the secretary of the district henceforward should be published together at least two weeks prior to each censors meeting, and

WHEREAS, By passing this resolution the Council in effect made a change in the by laws directly modifying Section 1 of Chapter I dealing with requirements for fellowship, therefore be it

RESOLVED, That Chapter I, Section 1, of the by laws of the Society be amended to read as follows

Section 1 Applicants for admission to fellowship in the Massachusetts Medical Society are required to satisfy the censors that they are not less than twenty-one years of age, that they are of sound mind and of good moral character, that they possess a good English education, that their names and addresses and the name and address of the secretary of the district society in which they reside have been published in a special list in the *New England Journal of Medicine* at least two weeks prior to their examination by the censors, that they have received a diploma from a medical school or college recognized by the Council, or that they have, in each instance, received the approval of the Committee on Medical Education and Medical Diplomas, that they do not practice medicine in a manner contrary to the Code of Ethics of this Society, and they shall appear personally before the censors and satisfy them that the above requirements are fulfilled.

Yours sincerely,

REGINALD FITZ, M.D

CHANGE NO 2

CHAPTER VI (DUTIES OF TREASURER)

Section 4

Paragraph 4 He shall attend the meetings of the Committee on Financial Planning and Budget, furnish the committee with such data as it may require and shall make all investments and reinvestments of the Society's funds with authority to buy or sell securities subject to the approval of this committee.

CHANGE NO 3

CHAPTER VII

Section 3

The Committee on Membership shall consist of five fellows It shall hold a stated meeting the week next preceding each council meeting and such other meetings as may be necessary

The committee shall consider all matters relating to honorary or associate fellowship, reurement, resignation, deprivation of the privileges of fellowship or remission of dues, and shall make recommendations to the Council concerning the same. It shall consider all petitions of fellows to be transferred from one district society to another in accordance with the provisions of Chapter III, Section 3

All bills incurred shall be countersigned by the chairman and forwarded to the president for his approval.

CHANGE NO 4

CHAPTER VII

Section 10

The Committee on Financial Planning and Budget shall consist of five fellows It shall hold a stated meeting during the week before the February meeting of the Council and such other meetings as may be necessary

It shall consider in a broad way how the Society can best use its income. Based upon such consideration it shall recommend to the Council at its February meeting the budget for the current fiscal year, after consideration of the estimates for expenses for the current fiscal year that have been submitted by individual members, the committees and officers of the Society It shall consider all requests for extraordinary appropriations and shall recommend to the Council whether or not they shall be granted.

Following the close of each fiscal year, this committee after consultation with the treasurer with the approval of the Council shall determine the amount to be refunded to the several district societies from the balance remaining in the treasury on December thirty first. This amount shall be apportioned among the district societies according to the number of annual assessments which shall have been paid to the district treasurers previous to March first.

All bills incurred shall be countersigned by the chairman and forwarded to the president for his approval

CHANGE NO 5

CHAPTER VII

Section 11

Reports of standing or other committees containing recommendations which may require mature consideration before their adoption shall be sent in abstract to the secretary of the Society, at least four weeks before their presentation to a meeting of the Council, for publication in the official organ of the Society

ings, the total number of neutrophilic polymorphonuclear leukocytes per cubic millimeter had the highest correlation with poor recovery

Interesting observations on blood studies as an aid in selecting cases of pulmonary tuberculosis for thoracoplasty are made by Muller (*Am Rev Tuberc* 35 83-98, 1937) Patients with marked activity as revealed by the leukocytic index and the sedimentation rate respond well to thoracoplasty if the trend of the blood as revealed by serial examinations indicates progressive improvement before the operation If, on the other hand, patients show an increase in the sedimentation rate and the leukocyte index, and a shift to the left on serial examinations, they do not derive the expected benefit from the operation and may even be harmed by it

Pinner and Woolley (*J Thoracic Surg* 5 476-480, 1936) call attention to the necessity of qualifying the term "negative sputum" by stating explicitly the methods used in the search for tubercle bacilli They hold that the unqualified term has as little meaning as have "normal renal" or "normal cardiac function" unless it is known by what observation or tests normality was assumed to exist One should specify as to negative sputum on direct smear, concentration culture or guinea-pig inoculation

B C G

The work done in western Europe with B C G immunization is reviewed by Kayne (*Am Rev Tuberc* 34 10-42, 1936) He concludes that this method is harmless, and is of some value if used under certain conditions as an adjunct to other means of prophylaxis He deplores the over-enthusiasm and the exaggerated claims of Calmette and his followers

Aronson and Dannenberg (*Am J Dis Child* 50 1117-1130, 1935) report on their studies at the Phipps Institute in Philadelphia over a period of seven years on 70 children vaccinated orally with B C G within the first ten days of life, and 167 non vaccinated children observed as controls Their observations indicate that the administration of B C G vaccine to newborn children exposed to patients with manifest tuberculosis may prove of value in reducing the mortality from this disease in infancy and childhood

Epstein, B (*Jahrb f Kinderh* 145 237-264, 1935) is skeptical as to the protective effects of B C G He still believes that separation from tuberculous persons is the best method of prophylaxis He adds, however, that administration of B C G should be continued, but only to children who are forced to live in tuberculous surroundings

Kereszturi and Park (*Am Rev Tuberc* 34 437-455, 1936) again report on their extensive

study of B C G vaccine as a prophylactic agent against tuberculosis in children Their evidence shows that the vaccine is harmless to animals and to human beings They conclude that since it increases considerably the resistance to tuberculosis, it should be advocated as a public-health measure for the prevention of tuberculosis in those who have not yet become infected, and who may later be exposed to it in their homes

TREATMENT

An illuminating discussion of the role of bronchoscopy in tuberculous tracheobronchitis is supplied by Samson (*Am Rev Tuberc* 34 671-699, 1936) He thinks that the widening recognition of this disease as a clinical entity demands that a bronchoscopic examination be frequently used for a final diagnosis In selected cases, bronchoscopic aspiration and chemical shrinkage of congested and edematous mucosa will give relief from distressing respiratory symptoms Occasionally such treatment is a life-saving measure In addition, bronchoscopic observation determines to a large extent what type of collapse therapy, if any, should be employed, since no form of collapse therapy should be used when ulcerative lesions are discovered in the bronchi

Buckles (*Am Rev Tuberc* 35 581-589, 1937) pleads for more frequent bronchoscopic examination in the routine treatment of chest disease Groups interested in diseases of the chest should organize better bronchoscopic services, as differential diagnosis is often dependent on bronchoscopy Much knowledge is to be gained from constant observation of the bronchi, and tuberculous patients may require the same bronchoscopic aid as do those with polyps, stenosis, carcinomas, ulcerations, bleeding points and bronchial obstructions due to other causes

SANOCRYSIN

Terril (*Am Rev Tuberc* 34 156-159, 1936) is one of the very few American specialists in tuberculosis to give the results of sanocrysin treatment He reports on only a small group, and recommends this measure as one supplementary to rest and collapse therapy

COLLAPSE THERAPY

Crimm and Strayer (*J Thoracic Surg* 5 441-443, 1936) urge that all patients with satisfactory collapse of the lung who have a positive sputum be bronchoscoped for possible stenosed bronchi or tuberculous tracheobronchitis

A statistical study compiled by Todd (*J State Med* 44 410-413, 1936) shows that when successful pneumothorax has been accomplished the expectation of life is increased by ten years Early diag

preserving the normal uncontaminated state of the tissues, a condition which operates to prevent more than 99 per cent of all initial infections acquired in the first fifteen years of life from producing fatal forms of tuberculosis during this period

The racial element is discussed by Pinner (*Am Rev Tuberc* 35 41-42, 1937) He asserts that no one single factor can explain or control the epidemiologic and pathogenic behavior of tuberculosis While it seems likely that race is important, living conditions in the broadest sense of the word are of greater significance, and many other factors, known and unknown, determine the course of events

Opie, McPhedran and Putnam (*Am J Hyg* 22 644-682, 1935) studied the exogenous infection of children and adults They found that among white persons exposed to open tuberculosis between birth and nine years of age, ten per cent of those living from twelve to fourteen years after exposure began have acquired the disease Among persons first exposed between the ages of ten and fourteen, 20 per cent living from 10 to 14 years after exposure have acquired it Of those exposed after fifteen, 10 per cent living from ten to fourteen years afterward have become infected The authors maintain that after the age of fifteen, infection is with a few exceptions of the adult type They think that the disease is then acquired by contact, and is not a continuation of the childhood type

Whitney and McCaffrey (*Am Rev Tuberc* 35 597-608, 1937) summarize the results of group tuberculin testing with purified protein derivative in the United States, applied to 56,688 individuals in thirty states and the District of Columbia The percentage of positive reactors in this study was 47 There were fewer positive reactors proportionately among six-year-old children than among those at any other age Following the sixth year of life, the trend of infection was generally upward at an average rate of over 1 per cent for every year up to the age of twenty Of particular interest is the fact that the percentage of positive reactors among the 8276 persons reported to have had contact with tuberculosis was 54.2, whereas only 33.3 per cent of those with no history of contact responded with positive reactions The infection rate for the contacts under five years of age was three times that for non-contacts in the same age group Nativity and parentage seemed to be significant factors in tuberculous infection among the white persons tested Native-born Americans of native parentage had 27.6 per cent positive reactors, whereas among the native-born of foreign stock 38.4 per cent reacted positively, and 61.2 per cent of the foreign-born did so

DIAGNOSIS

Lord (*New Eng J Med* 213 1181-1183, 1935), writing on the differential diagnosis of pulmonary tuberculosis, emphasizes the following clinical points

- 1 A family history of contact with tuberculosis or other opportunity for contagion may have an important bearing
- 2 A past or present history of hemoptysis out of a clear sky is especially suggestive of pulmonary tuberculosis
- 3 Primary pleurisy with effusion is equally significant

Tuberculin tests he considers most valuable in youth in screening out negative reactors, and he reckons the leukocyte count as of value because of the usual absence of leukocytosis in uncomplicated tuberculosis He stresses especially that physical signs may be negative with early active or indolent deep-seated lesions

White (*New Eng J Med* 213 1179-1181, 1935) considers the differential diagnosis of pulmonary tuberculosis and pulmonary circulatory changes. The following factors, he says, may be taken to indicate that the condition is of cardiac origin

- 1 A history of severe and prolonged substernal pain, usually necessitating morphine, with or without typical angina.
- 2 Enlargement of the heart, always present after coronary thrombosis and before failure.
- 3 Abnormal indications in an electrocardiogram, pointing to recent coronary thrombosis
- 4 X-ray evidence of enlargement of vessels at the hilum, often extending radially outward.
- 5 Preponderance of rales at the lung bases, or sometimes asthmatic wheezing with squeaks and groans.

He adds that pulmonary thrombosis or embolism with infarction may cause confusion with tuberculosis because of sudden chest pain and either hemoptysis or pleural exudate Careful study, however, will enable one to distinguish these conditions.

The interpretation of x-ray films of the chest receives consideration by Dunham (*Tubercle Am Sect* 17 33-38, 1935), who asserts that no one can make a diagnosis solely through them He finds that the misconceptions expressed by the terms "anular shadows" and "peribronchial" or "peritruncal" tuberculosis have almost disappeared Anular shadows are either real cavities or localized areas of emphysema, while truncal shadows usually have no relation to tuberculosis

LABORATORY STUDIES

Boissevain and Spillane, Jr (*Am Rev Tuberc* 35 661-662, 1937) have mathematically correlated blood counts and clinical symptoms with recovery from tuberculosis Among clinical symptoms amount of cough had the highest correlation coefficient with recovery Among the laboratory find

pneumothorax. When pneumothorax is impossible on either side, or adhesions cannot be cut successfully, bilateral thoracoplasty should be done.

According to O'Brien (*J Thoracic Surg* 5 123-131, 1935) there is no phase of the disease in which collapse therapy is not indicated, except the terminal one. In early lesions, the operation of choice is phrenic crushing. O'Brien warns, however, against leaving the patient in bed for an indefinite period after this operation. If improvement of the lesion is not apparent in a few weeks, pneumothorax should be added. In patients with unilateral, rapidly spreading soft lesions, in acutely ill patients, with multiple or large cavitation or extensive disease, and in tuberculous pneumonia cases with productive lesions with large thick-walled cavities, pneumothorax should be instituted at once. Thoracoplasty is necessary when cavities are not closed by the above procedures. While extrapleural packs may be used in a few exceptional cases, he advises against it.

Pollock and Forsee (*J Thoracic Surg* 55 509-524, 1935) recommend phrenicectomy as an adjunct to pneumothorax therapy. It is useful when adhesions cause cavities to remain open, when obliterative pleuritis occurs during re-expansion after completion of a successful pneumothorax, and in unsatisfactory pneumothorax due to a partially adherent pleura. They advise phrenicectomy also in order to close basal, central or hilar cavities when there are no apparent adhesions.

Urquhart (*Am Rev Tuberc* 35 443-463, 1937) reports on 542 thoracoplasty operations performed on 200 patients. His results are quite satisfactory, and he is distinctly optimistic as to the results following this operation. Of the 200 patients operated upon, the disease was apparently arrested in 59.5 per cent and 24 per cent were improved. Only 4 per cent failed to improve, and 12.5 per cent died. Most of the cases not yet in the apparently arrested group will as time goes on take their place there.

PNEUMONOCOINOSIS

Egbert and Geiger (*Am Rev Tuberc* 34 143-150, 1936) record a case of pulmonary asbestosis and carcinoma. A search of the literature failed to show a report of the coexistence of these conditions, although cancer does occur in cases of silicosis. The authors merely speculate as to the interrelation of the two processes.

Sokoloff (*Am Rev Tuberc* 34 700-711, 1936) studied 418 coal miners institutionalized because of chronic disabling pulmonary disease. He says that tuberculosis occurs more frequently in coal miners than was formerly believed. He suspects that this increase in tuberculosis is concomitant with changed working conditions in coal mines which

expose the workers not only to carbon particles, but also to a tremendous amount of fine silica particles. This combination produces anthracosilicosis rather than the pure anthracosis seen in the lungs of coal miners of twenty-five or thirty years ago. Thus tuberculosis was encountered in more than half the cases studied.

A definition of silicosis is attempted by Heffernan (*Tubercle* 16 397-405, 1935). He makes the following points:

1. Silicosis is a nodular fibrosis of the lungs produced by the inhalation of siliceous dust.

2. The interaction which produces silicosis is electrochemical and is caused by free silica. Mineral silicates, such as asbestos, when freshly pulverized into fine powder are also electrochemically active at the surfaces of the particles, and capable of acting in a similar manner to powdered quartz, but to a much more limited extent, setting silica partially free at the surfaces. Aqueous solutions of some silicates are systems containing, when freshly made, active silica hydrosol. Silicosis must be interpreted in chemical rather than in mechanical terms.

In another paper (*Tubercle* 17 250-255, 1936), Heffernan emphasizes the distinction between silicosis—the typical reaction of a healthy lung to inhalation of very fine silica dust—and dust retention—a comparatively passive process going on in diseased or damaged lungs subjected to the influence of any dust fine enough to be inhaled. Silicosis is an active dynamic process with a unique and specific histopathology. Healthy lungs can apparently deal with all forms of dust except free silica or certain combinations of silica like asbestos, which also may be capable of inducing chemical reaction.

Middleton (*Tubercle* 17 241-249, 1936) lists the occupations which constitute silicosis hazards. Among them are the pottery industry, sandstone and granite work, metal-grinding, sand-blasting, the manufacture of scouring powders, and coal-mining. In Great Britain the medical examination of workers exposed to certain kinds of dust, namely silica and asbestos, is obligatory. The physical requirements to be met are as follows: the chest must be of at least average development and the respiratory passages must be free from obstruction, there must be no signs of heart or lung disease, and there must be no evidence of tuberculosis.

MISCELLANEOUS

Moorman (*Am Rev Tuberc* 35 347-353, 1937) discusses the home versus the preventorium in the management of tuberculosis contacts. After viewing the question from many angles, he concludes that even though the results warrant an all-inclusive preventorium program, its cost makes it prohibitive. He urges a comprehensive dispensary scheme, which in addition to case-finding, family supervision and community education requires the

nosis is of course the all-important factor in prognosis. As to the ultimate prognosis, Todd is of the opinion that in the final analysis it depends largely upon the selection of cases and attention to detail during active treatment.

Gross and English (*Am Rev Tuberc* 35 303-322, 1937) advocate compression therapy for children with the adult type of active pulmonary tuberculosis. They found that juvenile patients did not do well when harboring this type. Mere routine rest in bed, plus a high-vitamin diet, has proved unsatisfactory in stemming the appalling death rate from this condition. They urge immediate compression therapy as soon as the adult disease appears, artificial pneumothorax being the procedure of choice. They add that one should not hesitate to do bilateral artificial pneumothorax if indicated. These patients are generally in need of such procedure, because the outlook without compression is extremely doubtful.

Early artificial pneumothorax therapy in minimal cases of tuberculosis is urged by Turner and Collins (*Am Rev Tuberc* 34 792-807, 1936). Reviewing their experience with 40 cases of minimal tuberculosis, they find that the operative risk is negligible, and that complications are so infrequent as not to constitute a deterrent for the use of pneumothorax in early cases. The conversion of sputum has been shown to be prompt and certain, and the percentage of cases with free space is high.

Certain danger signals in artificial pneumothorax therapy are listed by MacKay (*Am Rev Tuberc* 34 808-814, 1936). If free oscillations of the manometer on the negative side are obtained, accidents will be rare. Slight manometric fluctuations may be noted with the needle in the neighborhood of the parietal pleura, in the lung or air passages, or even in the pulmonary veins, and thus the utmost care must be taken in order to avoid accidents under such circumstances.

Stafford (*Am Rev Tuberc* 34 402-420, 1936) attempts to answer the very elusive question of when to terminate artificial pneumothorax treatment. He recognizes that in numerous cases the lung will frequently re-expand in spite of all the re-fills, the time of termination thus being arbitrarily settled. As to voluntary re-expansion of the lung, there are many pitfalls and problems. Among the factors requiring consideration are the extent and character of the pathologic process in the lung before compression, the clinical course of the disease before collapse, the constitutional condition of the patient at the time, the period since sputum was last free from tubercle bacilli, the economic status of the patient, and a general review of the indications for collapse therapy in the given case. A red-cell sedimentation rate may also be helpful in

determining whether there is activity in the collapsed lung. He wisely points out that, in general, with fairly light infiltrations occurring throughout a lobe and without cavitation the lung should remain collapsed for two or three years, although this practice cannot and should not be strictly adhered to. With heavy consolidations with or without thin-walled cavities the lungs should stay collapsed for at least four years, and dense fibrocaseous lesions with thick-walled cavities require five, six or more years to heal under compression.

Dufault (*Am J Roentgenol* 30 781-786, 1935) discusses the re-expanded lung. He agrees with many other writers that the type of lesion has more influence than has the extent. Exudative lesions may heal completely, leaving no scar. A period of three years does not seem to him too long a time to keep a collapse instituted for an exudative lesion in a young individual, nor is one of six or seven years too long for an ulcerocaseous process.

Dundee (*Brit J Tuberc* 30 55-61, 1936), treating the problem of when to terminate pneumothorax therapy, states that the longer the treatment, the fewer the relapses after re-expansion. He mentions the following factors as meriting consideration: (1) extent and nature of the original lesion (when there has originally been a large area of cavitation, pneumothorax should be continued indefinitely) and (2) behavior of the lesion as shown by x-ray during re-expansion. A complete x-ray serial of each case should be in the hands of the operator, as a tuberculous lesion often undergoes frequent radical changes during pneumothorax treatment. The most important change is reappearance of excavation, which calls for the immediate resumption of re-fills in order to close the cavity. The younger the patient, the greater the reason for prolonging treatment. In those who must return to hard manual labor, treatment should be continued considerably longer than with other patients, and often indefinitely. Pregnancy may be considered fairly safe during the fourth or fifth year of pneumothorax therapy, provided this is carried out for at least a year after pregnancy has terminated.

Coryllos and Ornstein (*J Thoracic Surg* 5 337-376, 1936) give a fairly detailed account of the management of bilateral cavernous pulmonary tuberculosis. No bilateral case, they hold, should be considered hopeless so long as one fourth of the lung parenchyma is free from disease. When bilateral apical cavities are present, bilateral pneumothorax should be attempted beginning on the more affected side. The authors oppose phrenicectomies and phrenicotomies. If pneumothorax is not possible on one side, thoracoplasty should be done after the opposite lung is satisfactorily collapsed selectively by

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24111

PRESENTATION OF CASE

A sixty-one-year-old American housewife entered the hospital complaining of dyspnea, cough and weakness.

For the month before entry she had noticed generalized weakness accompanied by a low-grade fever, loss of weight, dyspnea and a hacking unproductive cough.

Fifteen years before entry her gall bladder had been removed for chronic cholecystitis with cholelithiasis. She had been essentially well for the next twelve years, when on one occasion she expectorated about a teaspoonful of bright red blood. About two months later she had an attack of apparent bronchitis with a temperature of 103°F. At this time it was noted that her heart was fibrillating, but shortly thereafter the rhythm became normal. During the next two years she had occasional brief attacks of angina-like pain which were relieved by nitroglycerin. Her physician had noted a definite enlargement of the heart and loud systolic murmurs at the apex and base. She also had slight palpitation toward the end of this period, and she was therefore given digitalis, which she continued to take up to entry. A year and a half before entry, without preceding trauma, she developed an ecchymotic area over the right malleolus. The lesion slowly disappeared.

Her family history was noncontributory.

Physical examination revealed a well-developed, fairly well-nourished woman who showed evidence of weight loss. Above the left clavicle there were two walnut-sized, very firm nodules, one situated almost in the midline and the other lateral to it. The heart was enlarged, its rhythm was regular, and there was a loud systolic murmur at the apex. The blood pressure was 110 systolic, 70 diastolic. The lungs showed signs construed as representing less air going into the left than into the right. The liver edge could be just felt below the costal margin. There was no abdominal spasm or tenderness, and no masses could be palpated. There was slight tenderness in the right costovertebral angle. The temperature was 99.5°F, the pulse 88. The respirations were 24.

The urine had a specific gravity of 1.010 and contained the slightest possible trace of albumin. The

blood showed a red-cell count of 4,870,000 with 85 per cent hemoglobin, and a white-cell count of 10,100, with 72 per cent polymorphonuclears, 20 per cent lymphocytes and 8 per cent monocytes. The red cells and platelets were normal. Stool examinations were repeatedly negative. The non-protein nitrogen of the blood was 27 mg per cent. Culture of a catheter specimen of urine yielded bacillus coli. The blood Hinton test was negative. The sedimentation rate was 30, 46, 49, 50 mm with 58 per cent plasma.

X-rays of the chest showed no evidence of intrathoracic goiter or other mediastinal tumors. The trachea was in normal position. The lung fields were clear. The blood vessel markings of the lungs were rather prominent, and the heart shadow was considerably enlarged both downward and to the left in the region of the left ventricle. There was slight elevation of the left diaphragm with absence of respiratory motion during quiet breathing and limited motion during forced breathing. In a film taken at forced expiration the left lung was distinctly more radiant than the right. There was irregular density of the left lung root, along the course of the bronchus to the upper lobe. An intravenous pyelogram showed a rather low right kidney with very slight dilatation of the pelvis and some kinking of the ureter at the ureteropelvic junction. No other abnormalities were seen. There were slight proliferative changes about the bodies of the vertebrae. A gastrointestinal x-ray series was essentially negative. The liver shadow seemed somewhat enlarged.

An electrocardiogram showed a normal rhythm and sagging of all the S-T intervals. All the T waves were diphasic, possibly due to digitalis. Lead 4 was normal.

The patient remained in the hospital for a period of eight months and during the entire time her temperature showed a daily fluctuation between 99° and 100°F., occasionally rising as high as 101° or 102°F. and often falling as low as 98°F. Her pulse rate remained practically constant at 80. Examination of about 85 urine specimens showed a specific gravity varying between 1.010 and 1.030. None of them contained more than the slightest possible trace of albumin, and the sediments showed a few white cells, often a few red cells, but never casts. Several cystoscopic examinations were done, always with entirely negative findings, sterile cultures from both ureters and negative results from guinea-pig inoculation of the urine. The non-protein nitrogen never rose above 32 gm per cent. One serum protein determination was 6.4. The red count slowly sank to 3,750,000, the hemoglobin to 65 per cent. White counts ranged from 10,000 to 13,500 and the percentage of polymorphonu

breaking of contact by removing the patient, rather than the exposed child or children from the home. This does not apply to summer camps and prevention schools.

The principles and factors involved in manometric readings of intrapleural pressures in artificial pneumothorax are outlined by Peters, Pope and Hudson (*Am Rev Tuberc* 34 614-626, 1936). They make the following suggestion for general adoption in the construction of artificial pneumothorax apparatus for the purpose of bringing about greater uniformity and accuracy in practice and in recording intrapleural pressures. For the manometer and the tubing, they recommend a diameter of from 3 to 5 mm (average, 4 mm), for the pneumothorax needle they advise a 17 to 20 gauge (average, 18 or 19 gauge) needle from 5 to 6 cm long. The tubing should be as short as feasible, but of sufficient length to extend from the outlet of the pneumothorax apparatus to the needle when the latter is inserted in the chest.

Salkin, Cadden and McIndoe (*Am Rev Tuberc* 34 634-648, 1936) present an interesting study refuting the hypothesis of Coryllos regarding the closure of pulmonary cavities. They show that blocking a draining bronchus does not cause the healing of a cavity. They deny that the failure of an intra-bronchial lipiodol injection to enter a cavity means that there is no physical evidence of a cavity.

A case of pregnancy and successful parturition during the course of bilateral artificial pneumothorax is reported by Peters and Davenport (*Am Rev Tuberc* 35 71-82, 1937). They believe that pneumothorax therapy should never be discontinued because of an intercurrent pregnancy. It should always be considered among other therapeutic measures in pregnant women with pulmonary tuberculosis. In fact, they feel that in the presence of active progressive lesions it is more often indicated than is therapeutic abortion.

330 Dartmouth Street.

explain the increased brilliancy of the left lung. The glands in the neck are not calcified. The films of the skull are negative. The kidney outlines are quite distinct. She has a low right kidney with some increase in size of the pelvis on that side which usually happens when the kidney is low. There is nothing unusual in its shape. I do not see anything suggesting stones or disease of the kidney other than slight dilatation of the pelvis of the right kidney.

DR TRACY B. MALLORY: It has occurred to me why that second set of x-rays of the hands was taken. The question of sarcoid had been raised at one period.

DIFFERENTIAL DIAGNOSIS

DR. BAUER: The x-ray changes in the terminal phalangeal joints are those of degenerative arthritis. These we see in most women sixty-one years of age. There is no suggestion of a destructive lesion such as we see in sarcoid.

It would appear that we are dealing with a woman who had an unexplained fever which continued throughout her hospital stay. The only obvious finding on physical examination at the time of entry was a definitely enlarged heart without obvious cause, that is, she had no evidence of valvular heart disease or of hypertension. She did give a history of angina-like pain relieved by nitroglycerin. I presume the most reasonable explanation of the cardiac enlargement would be hypertrophy secondary to sclerosis of the coronary arteries.

As I went over this case history I thought that some disease commonly associated with erythema nodosum was the most likely cause of this patient's illness and death. The description of the recurring skin lesions seemed more in keeping with a diagnosis of erythema nodosum than with a diagnosis of erythema induratum. I have always considered the lesions of erythema induratum as being painless. These lesions recurred and did leave some scarring. Thinking that we were dealing with an individual who had had recurrent attacks of erythema nodosum, I thought it wisest to consider seriously the two diseases most commonly associated with erythema nodosum, namely rheumatic fever and tuberculosis. I rather wished as I went over the history, that the pathologist had not told us what he had found in the gland and skin, feeling that since he had given us this information probably the diagnosis of tuberculosis was not adequate.

I cannot understand why her urinary tract was so thoroughly investigated on repeated occasions. The urine did contain a slight trace of albumin and a few white and red blood cells but never any

casts. From reading the case report I thought a low kidney was adequate explanation for the slight dilatation of the pelvis and the kinking of the ureter observed. I cannot believe that she had any serious infection of the genitourinary tract. A mild cystitis would best fit the findings. I should not have expected washing of the kidney pelvis to bring about such a dramatic improvement of the skin lesions. The relief experienced was coincidental rather than cause and effect.

Is there anything in this case history to enable us to make a diagnosis of rheumatic fever? I should say no. This woman did run a low-grade fever, the pulse, however, was always 80. There is nothing in the story which suggests rheumatic fever to me. She did have this one attack of arthritis which I think was more likely part and parcel of the erythema nodosum than a manifestation of rheumatic fever. Can we explain this clinical picture on the basis of tuberculosis? She did give a history of expectorating about a teaspoonful of bright red blood three years prior to this last hospital entry. Two months later she suffered from what was diagnosed bronchitis. At this time a small tuberculous peribronchial lymph node may have broken down and eroded into a bronchus with the resulting slight expectoration of blood. If this occurred she may have had a slight tuberculous pneumonia resulting secondarily. We know that the physician in charge suspected that the nodes present in the supraclavicular region might be radiosensitive. That they did not represent any form of lymphoma was clearly demonstrated because x-ray treatment resulted in their breaking down. This fact plus the persistent sinus leads one to suspect that the nodes were tuberculous. Subsequent removal of one node proved that it was tuberculous. Is it possible that we are dealing with an individual who had tuberculosis involving the supraclavicular and tracheobronchial lymph nodes? Could caseation and erosion of one of these nodes explain the pulmonary symptoms that she had three years before entry? If she did have an erosion of one of the bronchi and a breaking down of a lymph node it might possibly be that tubercle bacilli were entering the blood stream from time to time. That of course is a guess. One does have to bear in mind the possibility of Hodgkin's disease. We know that Hodgkin's disease is intimately associated with tuberculosis at times. Some workers have succeeded in isolating tubercle bacilli from Hodgkin's lymph nodes and therefore concluded that tuberculosis was the etiologic agent. We further know that Hodgkin's disease often follows tuberculosis. I think I am right in saying that in some glands you can demonstrate both, is that right?

clears from 79 to 92 per cent. No abnormal cells were ever found in the smear. Several blood cultures showed no growth and agglutination tests for typhoid and bacillus abortus were negative.

Shortly after entry she was given 1200r units of x-ray radiation over the gland in her neck and 600r over her chest. A subsequent x-ray examination of the chest showed better aeration of the left lung.

About two weeks after entry she began to complain of an irritating sensation in the palm of the left hand and in the left elbow. A week later the right wrist, the left ring finger and the left elbow became swollen and red. X-rays showed no abnormalities of the bones or soft tissues in these areas but several terminal phalangeal joints showed narrowing of the joint spaces and proliferative changes about the joint margins. Within a few days all the joints in her body began to ache and simultaneously many reddish, slightly indurated, tender spots about the size of a dime appeared on her legs, arms and body. At this time one of the cystoscopies was performed and the pelves of the kidneys were injected with 2 per cent mercuriochrome. A remarkable improvement in her symptoms followed, the temperature dropped, the joint pains disappeared and the skin lesions regressed, leaving only indefinite slightly depressed scars. In the course of ten days, however, the symptoms recurred and new skin lesions developed. A second cystoscopy with dilatation of the ureters was followed by another remission in symptoms, this time of longer duration.

Meanwhile the gland in the neck which had been treated by x-ray began to show signs of breaking down. About three months after entry it began to ooze purulent material and two weeks later it was curetted but the material was too necrotic to permit a histologic diagnosis. The swelling was relieved by this treatment but a persistent sinus developed. Her general condition improved, though fever continued and new crops of skin nodules appeared. These were, however, smaller and less tender than the earlier ones.

In the middle of her fifth month in the hospital it was noted that her spleen was palpable 3 cm below the costal margin. X-rays of the chest and hands showed no changes from the previous examinations. At this time a small lymph node from the neck and a strip of skin from the leg were biopsied. The node showed findings consistent with tuberculosis. The skin from the leg showed appearances consistent with erythema induratum.

During the sixth month new skin lesions appeared, the splenic enlargement persisted and she complained for a brief period of left facial neuralgia. X-rays of the teeth, skull and sinuses were

negative. In the seventh month a palpable lymph node appeared in the right supraclavicular region. She also had occasional night sweats coincident with somewhat higher elevations of temperature. Some nonproductive cough and much abdominal distress with gaseous eructations disturbed her, but her general condition changed little. A chest plate at this time showed a change in the slope of the heart shadow. It seemed rounder, due to an increase in width across the auricles and a decrease in length. The lung fields remained about the same although the question was raised of some increased prominence of the vascular markings.

During her last month in the hospital her condition remained essentially unchanged. She was discharged, however, after eight months still febrile, but her weight and strength seemed about the same as on entry. The sinus in her neck seemed almost healed and her extremities were free from skin lesions. Her lungs were normal, the heart unchanged, the liver and spleen still palpable.

For two and a half weeks after returning home there were no developments. Then, suddenly one morning she began to complain of pain and a feeling of tightness in her chest "as if some one were sitting on her." The nurse noted that she was short of breath, that her skin was clammy and her pulse thready. When seen by her physician two hours later the attack had completely subsided and no physical abnormalities were noted. She had another similar attack the next day and a white count showed 14,000 cells. Two days later a loud friction rub could be heard over the pericardium and the following day she died.

X-RAY INTERPRETATION

DR GEORGE W. HOLMES: The obvious things are the increase in size and the change in the shape of the heart shadow seen in several of the films, also an increased brilliancy of the left lung compared with the right. I do not believe that it is due to rotation. It is not constant. It is seen in the first film but not in the last. I can only call attention to it. I do not know what it means. We expect such a change to be due to partial obstruction of the bronchus, but it is not constant. The heart lesion is definite. There is hypertrophy of the ventricles and enlargement of the auricles. There are a few small calcified glands at the lung roots. Otherwise we get no help from this examination.

DR WALTER BAUER: Do you see anything in the mediastinum suggesting glands? How about the irregular line of density mentioned in the report?

DR HOLMES: I suppose they were trying to

the atheromatous deposits in this area become calcified and feel like little shotty nodules when you palpate them at autopsy. It is seldom that these calcified masses are large enough so that one could even imagine that they would have produced narrowing of the mitral valve. In this case, however, there was so much calcification that it appeared that the mitral valve had been definitely stenosed by the calcified mass. The heart was hypertrophied, weighing 460 gm., and we found nothing to explain the hypertrophy. The spleen was normal in size, weighing only 140 gm. I find it a little hard to believe that it was felt. Spleens are seldom palpable until they reach 400 gm.

A PHYSICIAN: Was there anything in the kidneys?

DR. MALLORY: No.

CASE 24112

PRESENTATION OF CASE

First Admission A forty-three-year-old American letter carrier entered the hospital with the complaints of weakness, hematemesis and melena of one day's duration.

One year before entry he began to have nocturia two or three times a night without diurnal frequency or other urinary symptoms. About that time he began to notice slight dyspnea on climbing a flight of stairs. Eight months before entry he had an attack of severe steady, cramping pain in the left costovertebral angle which lasted about fifteen minutes and was associated with a desire but inability to move his bowels and void urine. He took some soda and vomited, with complete relief of the pain. Subsequently his urine was said to have been bloody. During the month before entry he had two other entirely similar attacks one of which was right sided. Following each of these attacks his urine was quite definitely bloody. About three weeks before entry he began to have moderately severe frontal headaches almost daily. They were relieved by Anacin tablets and were never severe enough to keep him from work. On the day before entry he had two black bowel movements. He continued his work that day but the next morning felt a little tired. That afternoon he passed another large, black, tarry stool. After supper that evening he slept for a while but was awakened by sudden epigastric distress. He felt nauseated, vomited a large amount of blood and immediately thereafter became unconscious. He had had no previous epigastric distress, nausea, hematemesis or melena, and never any jaundice. Except for the slight dyspnea mentioned above he had had no cardiorespiratory symptoms. Physical examination revealed a well-developed

and nourished, extremely pale man who was unable to respond clearly to questions. The ocular fundi showed marked narrowing and tortuosity of the arteries with numerous flame-shaped hemorrhages and white patches of exudate. The heart was slightly enlarged to the left, the rhythm was regular, and the sounds were of good quality. A_2 was greater than P_2 , and there was an apical systolic murmur. The blood pressure was 160 systolic, 90 diastolic.

The temperature was 99.5°F., the pulse 90. The respirations were 20.

The urine had a specific gravity of 1.020 with the slightest possible trace of albumin and a normal sediment. The blood showed a red-cell count of 2,000,000 with 45 per cent hemoglobin and a white-cell count of 9000 with 74 per cent polymorphonuclears. The stool gave a ++ guaiac test. The nonprotein nitrogen of the blood was 53 mg per cent and the chlorides were equivalent to 100 cc. of N/10 sodium chloride. The blood Hinton test was negative.

He was given a clysis and a transfusion of 250 cc of blood as soon as possible, and in the next three days was given four more transfusions of 250 cc each. On the day following entry his blood pressure had fallen to 112 systolic, 60 diastolic, but on the fifth day it had risen to 240 systolic, 140 diastolic. Clinically he improved rapidly on a first-stage gastric diet, and was entirely symptom free. His diet was gradually changed to solid foods and he was discharged on the thirty-seventh day in reasonably good condition with a red-cell count of 3,400,000. Repeated urine examinations during his stay in the hospital showed a maximum concentration of 1016 with the slightest possible trace to a trace of albumin and occasional casts in the sediment. On the eighteenth day the nonprotein nitrogen of the blood was 22 mg and the serum protein 5.6 gm per cent. On the day of discharge a urine concentration test gave a maximum specific gravity of 1.012, and a phenolsulfonephthalein test of kidney function showed a total excretion of 35 per cent in one hour with only 10 per cent being excreted in the first fifteen minutes. His stools had become guaiac negative ten days after entry. An x-ray of the chest taken three weeks after entry showed the heart hypertrophied in the region of the left ventricle but somewhat decreased in height. The aorta was tortuous and elongated. A gastrointestinal series done at the same time showed a normal esophagus and stomach. The first portion of the duodenum was spastic and difficult to visualize. When filled it appeared to be deformed near its apex but no ulcer crater could be demonstrated. There was a rounded mass of barium in the region of the lower jejunum which could have

DR MALLORY Yes

DR BAUER So there is a possibility that we are dealing with an individual who has, in addition to a tuberculous lymphadenopathy, Hodgkin's disease

Her manner of death I suppose is probably best explained on the basis of coronary occlusion, although I wish we had a little more information concerning it. I think it is only right to point out that if she had tuberculosis of the lymph nodes of the mediastinum and tracheobronchial nodes, direct extension to the pericardium would result in a tuberculous pericarditis with effusion. If such occurred it would be an adequate explanation for the type of exitus described. I was inclined to make a diagnosis of tuberculous adenitis involving the tracheobronchial lymph nodes with an associated erythema nodosum. There is a definite possibility of miliary tuberculosis. In view of the past history it would be safer to say that she died of coronary occlusion, but there is a possibility of the whole clinical picture including the manner of exitus being explained on the basis of tuberculosis. There is nothing in the case report to suggest the possibility of the existence of any form of lymphoma. I can go no farther.

DR MALLORY Are there any suggestions?

DR WYMAN RICHARDSON Would Dr Bauer consider a diagnosis of bacterial endocarditis?

DR BAUER In an individual with unexplained fever of this duration one should always consider it. I did not think there was much to suggest it other than the long-continued fever. It is certainly not a characteristic history of subacute bacterial endocarditis. Is there anything in the history that suggests it to you?

DR RICHARDSON I do not see how you explain the gradually increasing size of the spleen unless you think she had tuberculosis of the spleen.

DR BAUER I think there is a good possibility of such being the case.

DR RICHARDSON Then there is a suggestion that she has had difficulty with her heart.

DR BAUER Yes, she had an enlarged heart which in light of the history I believe was due to sclerosis of the coronary arteries rather than to rheumatic heart disease.

DR DONALD S KING I have an impression that erythema nodosum with miliary tuberculosis is a disease of young and not old people.

DR MALLORY Dr Goodman, can you tell us about that?

DR JOSEPH GOODMAN For the most part it occurs in younger individuals and that also holds for erythema induratum, which was the other possibility raised. The fact that there was some scarring after the skin lesions disappeared certainly is a point

against erythema nodosum. I think these lesions might also be considered papulonecrotic tubercles, which usually leave scars and small scales such as described in this case.

DR BAUER I entertained the possibility of tubercles. I thought five or six recurrent attacks were most unusual, and I also thought that some of them would probably have broken down.

A PHYSICIAN I did not know that tubercles were as painful as that.

DR GOODMAN They may be painful. They usually break down. I must admit that if they were tubercles one has to consider the description inadequate in certain respects.

CLINICAL DIAGNOSES

Tuberculous adenitis
Coronary thrombosis

DR. BAUER'S DIAGNOSES

Tuberculous adenitis
Erythema nodosum
Tuberculous pericarditis with effusion?
Coronary thrombosis?
Miliary tuberculosis?

ANATOMICAL DIAGNOSES

Pericarditis, acute fibrinous, tuberculous
Tuberculous lymphadenitis, mesenteric and bronchial
Tuberculosis of pancreas
Pulmonary tuberculosis, healed, Ghon's tubercles.
Hydrothorax, bilateral
Cardiac hypertrophy
Arteriosclerosis, slight aortic
Calcification of posterior leaflet of mitral valve.
Operative scars Cholecystectomy, appendectomy

PATHOLOGICAL DISCUSSION

DR MALLORY I do not believe I can add any more information on the skin lesions. They were quite superficial. They did not look particularly like tubercles and I inclined to erythema induratum rather than nodosum from the histological examination of a single lesion.

The autopsy showed that the cervical lymph nodes and the tracheobronchial nodes contained extensive tuberculosis. The lungs were free from it except for a calcified Ghon's tubercle. The pericardium showed an extensive pericarditis which proved to be tuberculous. There was no endocarditis and no coronary thrombosis. The coronaries were free even from atheroma. There was one peculiar finding in the heart. The commonest spot for atheroma in the body is the posterior surface of the long cusp of the mitral valve and often

does not look cachectic or show other evidences of malignancy, and cause massive gastric hemorrhages. The x-ray examination, however, gives no support to such a diagnosis whereas, on paper at least, it suggested that he might well have had a duodenal ulcer. Certainly he had very active bleeding from the stomach, and I should favor a duodenal ulcer.

We have definite evidence of hypertension and of hypertensive heart disease, characterized by an elevation in blood pressure and enlargement of the left ventricle clinically and by x-ray, although the heart is not greatly enlarged in size, it does look like a heavy heart. Then the symptoms he complained of—shortness of breath on exertion, inability to lie flat at night, and edema, seem to be due to heart failure. His vital capacity was diminished, 1700 cc., and he had rales at the lung bases. He was not showing acidosis, and his serum protein was 5.8. So I think the signs of failure were linked up with the cardiac situation.

There does seem to be evidence of chronic nephritis. The fact that he had frequency at night and not in the daytime is suggestive of nephritis. He had a high nonprotein nitrogen throughout his illness on all tests except one, which was 22. I cannot account for that one. I think we must follow the others in which it was elevated. He had a renal function of 35 per cent in one hour, only 10 per cent being excreted in the first fifteen minutes. He should have had at least 25 per cent in the first fifteen minutes, and we would expect a renal function of 50 over the course of an hour. He had retinal hemorrhages and headaches and albumin in the urine. He apparently died in uremia, and prior to death there was an acute pericarditis. I think these things seem fairly obvious from the record.

However, there does seem to be an underlying intercurrent group of symptoms that would seem to need some explanation. At the first entry we have the story of severe, steady cramping pain in the left costovertebral angle which lasted about fifteen minutes and was associated with the desire but the inability to void. Following this and following several other attacks he passed bloody urine. Then there is also a story that on one occasion he had right-sided pain and later on some lumbar pain. These facts suggest to me—though I may be reading something into the record that does not belong here—an intermittent hydronephrosis with pain, with oliguria, and with relief of pain on passing urine and in the urine there were red blood cells. If it were just from hydronephrosis, however, I do not see why he should have so much kidney damage. Another possibility we must think of is renal tumor. If he had a hypernephroma I think he probably would

have been a person who had the appearance of having cancer. He would have been cachectic. Then there is the possibility of polycystic kidneys. The reasoning would be that he had a great number of cysts in both kidneys and the renal cortex would be destroyed by pressure, causing a chronic nephritis. If the kidneys became large enough, moreover, they could become movable and therefore their weight might kink the ureters, giving a period when he would have a urinary obstruction and pain due to increased pressure within the renal pelvis. When the kink straightened out it would permit the passage of urine, and frequently such urine contains a considerable amount of blood. There is nothing said in the history of any abdominal examination so we may assume that nothing was felt, but polycystic kidneys may be missed on physical examination. There is no mention of investigation of the genitourinary tract. I feel that that group of symptoms needs some explaining, and that is the best explanation I can give for them. I have seen a few cases of polycystic kidneys and I remember two that were entirely missed because the presenting symptoms were those of hypertensive heart disease or nephritis with hypertension. I think Dr. Mintz has looked up a series of these cases here at this hospital and many patients with polycystic kidneys had hypertension. My diagnoses would be chronic nephritis with terminal uremia, acute pericarditis, hypertensive and arteriosclerotic heart disease, with congestive failure, duodenal ulcer and polycystic kidneys.

DR. TRACY B. MALLORY: It is always a good deal of a gamble to try to guess what form of renal insufficiency a patient of this sort has. Does anyone else want to hazard a diagnosis?

DR. WYMAN RICHARDSON: I would raise the question of repeated renal infarcts.

DR. MCGINN: I think that most renal infarcts are painless. I admit that should be considered.

DR. JAMES H. MEANS: I wonder if it could be vascular nephritis with intermittent bleeding and consequent variation in the urinary output.

DR. FLETCHER H. COLBY: The specific gravity is pretty high for polycystic disease.

CLINICAL DIAGNOSES

Malignant hypertension
Congestive heart failure
Uremia
Hypertensive encephalopathy
Fibrinous pericarditis
Duodenal ulcer

DR. MCGINN'S DIAGNOSES

Chronic nephritis
Hypertensive heart disease

been a diverticulum. Repeated gastrointestinal series showed a definite ulcer scar on the posterior wall of the pyloric valve. It had a crater measuring 1 cm in diameter and was thought possibly to be active.

Second Admission (nine weeks later). About a week after discharge he had gradual loss of vision over a period of one day. However, his vision improved somewhat during the next four days but remained sufficiently poor so that he had difficulty in walking alone. This condition persisted up to the time of re-entry. During the two months between entries he had gradual but steady increase in his dyspnea on exertion, and he had moderately severe headaches almost daily. On several visits to the Out Patient Department the blood pressure readings averaged 240 systolic, 150 diastolic. During the ten days before re-entry he had three or four attacks of sharp pain across the lumbar region which lasted about an hour. During each of them he felt as if he wanted to void, but did not do so. His nocturia persisted and for the week before re-entry he had voided pale-red urine. Also during the week before re-entry he had been unable to sleep lying flat because of his dyspnea. For several days he had had ankle edema. He had had no cough, hemoptysis, chills, sweats, paroxysmal nocturnal dyspnea or gastric symptoms.

Physical examination revealed a well-developed and nourished, somewhat pale man sitting up in bed in mild respiratory distress. The physical examination was essentially the same as on the previous entry except that there were diminished breath sounds, slight dullness and rales at both lung bases and some edema of both ankles. The blood pressure was 238 systolic, 154 diastolic.

The temperature was 99°F, the pulse 110. The respirations were 30.

Repeated urine examinations showed a maximum specific gravity of 1.018 and a slight trace to a large trace of albumin. Many of the specimens were loaded with red cells, and many contained a few casts. The blood showed a red cell count of 2,800,000 with a hemoglobin of 55 per cent, and a white-cell count of 9000 with 79 per cent polymorphonuclears. The guaiac test on the stool was negative. The nonprotein nitrogen of the blood was 60 mg and the protein was 5.8 gm per cent. The vital capacity was 1700 cc. An electrocardiogram showed abnormal T waves which might have been due to digitals (digitalization was started immediately on entry six days before this tracing). There was no axis deviation.

He had a very good diuresis but at the end of the first week began to hiccough and vomit frequently. At that time the nonprotein nitrogen had risen to 100 mg per cent and the CO₂ combining power of the blood was 72 vol. per cent. In spite of CO₂ inhalations he continued to hiccough and

vomit and on the fifteenth day his blood chloride was equivalent to 88 cc of N/10 sodium chloride, and his CO₂ combining power was 68.6 vol. per cent. However, his nonprotein nitrogen had fallen to 75 mg per cent. He was given several transfusions and clyses but failed to show much improvement. On the twenty-eighth day he rather suddenly became very much worse. He became semistuporous, had severe itching of the skin, shouted a good deal, was very restless and became completely blind. Four days later a pericardial friction rub could be heard and he died on the next day. A week before death the nonprotein nitrogen was 98 mg per cent.

X-RAY INTERPRETATION

DR AUBREY O HAMPTON. I do not see a definite variation from the normal in the first examination and I agree with the examiner that there was no evidence of ulcer. The second examination shows a small fleck in the region of the pyloric valve which I do not believe I would call an ulcer. It is more likely to be the pyloric valve on end.

These examinations are fifteen days apart, and I cannot imagine the pylorus being normal at the first examination and looking like a healing ulcer at the second examination. If this is an ulcer, I do not believe it had anything to do with the previous symptoms.

DR SYLVESTER MCGINN. Could they have formed another impression from fluoroscopy?

DR HAMPTON. Yes, but this is a good film of the area they were speaking of. His chest film taken two weeks before death shows obliterated costophrenic angles on both sides. There is some thickening of the pleura along the axillary lines. The lungs are clear except for apical scars. His heart is blunt in the region of the left ventricle. The decrease in height that was mentioned must mean that the heart is round in shape. It is not a dilated heart. It is hypertrophied without dilatation. I think the transverse diameter is within normal limits. It looks like the heart and aorta of hypertension.

DIFFERENTIAL DIAGNOSIS

DR MCGINN. On reading this over I felt there were certain things in the history that were at least fairly obvious. Dr Hampton's comment on the gastrointestinal series has made some of them a bit more dubious. However, in spite of his interpretation I cannot disregard the story on the first admission of the vomiting of a considerable amount of blood, and of melena. Since nothing develops to make us believe the patient had esophageal varices there are two things that could cause such a condition, a tumor of the stomach, or an ulcer. Sarcomas, in particular, may begin to produce symptoms rather abruptly, even in a man who

NURSING EDUCATION IN NORTH ADAMS

THE *North Adams Transcript* of December 11, 1937 described an experiment which has been planned and will soon be undertaken at the North Adams Hospital to meet a community nursing need. The project presents several novel features. Its purpose is to furnish Grade A nursing care at a cost of about twenty-five dollars a week, and the School of Private Duty Nursing, now newly established, will give an intensive eighteen months course in bedside nursing. Classes will be admitted in January, April and September. The educational requirements for admission will be two years of secondary school, not more specifically described but presumably meaning two years of

ordinary high school. This project "aims to offer first-class bedside nursing care to people of modest means and at the same time provide throughout the country a livelihood to thousands of women unable to obtain a place in the economic world as self-supporting citizens."

It is emphasized that the project differs fundamentally from some suggestions made by a number of thoughtful students of nursing education elsewhere, in that its object is not to develop the inferior grade of nursing skill or subsidiary nursing service which they have recommended, but to place the "service on the highest possible level of skill and intelligence" at a distinctly lower cost. This aim is certainly praiseworthy, and if the goal can be reached, the experiment will prove to be a most welcome contribution.

The problem we have here is not new. It is the one presented by divergent views as to the best preparation for the practice of a profession. How broad and deep should the foundations be? While the Grade A nursing service is not defined, the designation suggests that it is at the highest level, commonly understood to be the highest that the nursing profession can supply. Yet a grade of nursing higher than Grade A is indicated by the statements that the "plan will not provide substitutes for highly trained professional registered nurses, whose services will be required by all local physicians as at present," and that "the school itself will open up to such nurses permanent employment as members of its faculty so to speak, for the training will be given entirely by a carefully selected and organized staff of experienced graduates in the nursing profession."

The new project takes issue sharply with the current view that the Grade A nurse should have a four-year high-school course, supplemented by three years in a school of nursing in which, whatever the content of the course, instruction should be at the collegiate level. It is commonly thought that an educational foundation of two years of high school is too narrow and superficial to bear the weight of the superstructure now required in the education of a Grade A nurse.

Congestive failure
Uremia
Fibrinous pericarditis
Duodenal ulcer
Polycystic kidneys

ANATOMICAL DIAGNOSES

Arteriosclerosis, coronary, aortic and cerebral
Pericarditis, acute fibrinous
Cardiac hypertrophy, hypertensive type
Chronic passive congestion
Pulmonary infarct
Bronchopneumonia

PATHOLOGICAL DISCUSSION

DR MALLORY I feel quite sure polycystic disease could give every symptom this patient had. A typical clinical picture of malignant hypertension and also hematuria is not uncommon. What we found, however, was malignant vascular nephritis. The kidneys weighed 225 gm. They were rather markedly scarred on the surface with a coarser type of scarring than is usual with the ordinary benign vascular nephritis. The lesions in the blood vessels were exceptionally acute in character and they involved predominantly the intermediate-sized blood vessels, the radial arteries rather than the afferent arterioles of the glomeruli.

That is characteristic of the so-called malignant type. These cases ordinarily do not have any severe grade of hematuria but they occasionally develop quite massive hematuria. This may be unilateral, and kidneys have been removed because of it. I think his pain probably arose from the presence of clots in the pelves and ureters because we found no hydronephrosis.

DR MEANS I remember that, when I was a medical student in Dr Cabot's case history course, he stated that cases showing what was then called chronic interstitial nephritis—which was the same thing as vascular nephritis, I fancy—might give rise to renal apoplexy, so to speak, with a considerable hematuria.

DR MALLORY Yes, I think there is no question that it does occur. Exactly what the mechanism is, I do not know. There were no fresh infarcts in the kidney.

DR HAMPTON Did he have an ulcer?

DR MALLORY At the time of autopsy a very shallow depression 1 cm in diameter and 1 mm in depth was found in the first portion of the duodenum, but sections through it were negative so I do not believe it was an ulcer.

A PHYSICIAN Where did he bleed from?

DR MALLORY We found nothing to explain it. Terminally he had uremic gastritis and colitis, but I do not believe he had had them any long period of time.

as a member of the triumvirate. This was next door to Osler's home, which was 1 West Franklin Street. Osler succeeded in retaining Futch in Baltimore when the offer came to take Dr. Graham's old place at the University of Toronto. After Osler went to England, Futch kept in close touch with him. Futch married in 1909 the daughter of Osler's old teacher, Dr. Palmer Howard. This bound Futch still closer to the Osler household. His children were always great favorites of Dr. Osler. One son, Dr. Palmer Howard Futch, is now following in his father's footsteps as resident physician at the Johns Hopkins Hospital.

During the War, Futch served as a lieutenant-colonel in the Canadian Army Medical Corps and during the winter of 1917-1918 was in charge of the Medical Division of No. 16 Canadian General Hospital, Orpington, Kent, England. Futch's medical work was largely concerned with teaching. He did, however, contribute to medical literature, writing the sections on diabetes and gout in Osler's *Modern Medicine*. He was particularly interested in diseases of metabolism and endocrinology. A forceful, clear teacher, he will long be recalled by his students. His colleagues will remember him for his sound judgment and for his delightful, rather reserved personality. He was a man who read extensively and had a wide knowledge of world affairs. He carried on the traditions set by Osler in a worthy style.

CASE HISTORY No. 63 PARTIAL PLACENTA PREVIA

Mrs. M., a twenty-five-year-old primipara approximately thirty weeks pregnant, telephoned on January 23 at 12.30 p. m. that she had just had a discharge of blood from the vagina which she estimated at about a cupful. There was no pain. She was advised to come into the hospital immediately, no visit or examination was made at home.

There was no family history of tuberculosis, diabetes, cancer or hemorrhagic disease. She had

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

measles, mumps and scarlet fever as a child, and her tonsils and appendix had been removed. Catamenia began at twelve, regular twenty-eight-day cycle, lasting five days without pain. Her last period was June 24, making the estimated date of confinement March 31. There had been a slight show of blood on January 9 which was considered to have followed coitus. At six prenatal visits her urine and blood pressure were normal.

The patient was transported to the hospital by ambulance. Upon entrance her temperature was 99.6° and pulse 80. She was a well-developed and nourished woman. The mucous membranes were not pale. Her heart was not enlarged and there were no murmurs. Her lungs were resonant throughout and there were no rales. Her pelvic measurements were normal as were her extremities. The fundus was halfway between the umbilicus and the ensiform cartilage, agreeing in size with her menstrual date. The fetal heart tones were regular and strong, rate 152. Palpation revealed the baby in breech position with the sacrum left posterior. She was still bleeding but not profusely. The uterus was soft; the patient was not in labor. Because there had been a hemorrhage and because the patient was still bleeding, even though the pregnancy was advanced only to a point where the viability of the child was extremely doubtful, vaginal examination was deemed necessary to determine the source of the bleeding. A bagging kit was prepared before the examination which revealed a cervix partially taken up and dilated about 4 cm. The edge of the placenta was felt on the left of the cervix. The membranes were already ruptured. Examination definitely increased the bleeding and it was deemed wise to insert a bag. Under nitrous-oxide anesthesia a Voorhees bag No. 5 was inserted into the uterus and placed so that it lay over the partial previa. This was done at 2.20 p. m. Labor started almost immediately. The fetal heart remained of good quality until 4.30 when it dropped below 100 where it remained until delivery. The cone of the bag appeared at the vulva at 5.20 p. m., and immediate delivery was decided upon.

Following the removal of the bag, about a pint and a half of clots were expelled. A foot was found in the vagina and a breech extraction was performed. The baby weighed 3 lb., 9 oz., breathed feebly but could not be made to cry. However, with oxygen and carbon dioxide it developed a good pink color. On account of the persistent bleeding following the birth of the baby, the entire placenta, with membranes complete, was manually removed. The uterus reacted normally and no abnormal bleeding followed. The patient's

There is widespread recognition of a serious problem in nursing, namely, how to meet the nursing needs of the community in a more nearly adequate manner than at present. It is to be expected that many solutions will be suggested, not all of them sound or practicable. But due credit should be given for every attempt to make progress, and the results of the experiment in North Adams will be awaited with interest.

LIPOID PNEUMONIA

THE dangers of oily preparations used for nose drops, especially in infants, have been the subject of considerable comment in the recent past, and a renewed warning is now issued in the *Quarterly Bulletin* of the City of New York Department of Health, on account of the enormous increase in the use of such preparations.

Not only is the danger of the inhalation of oily substances used as nose drops a real one, but other agents have also been found to cause trouble, codliver oil and even cream having been involved in some of the cases reported. Consequently, mothers should be warned not to give codliver oil or other substances of a similar nature to struggling infants or to very feeble ones.

Fatal cases of pneumonia caused by the aspiration of oils have been reported in the American medical literature since 1925 in sufficient numbers to warrant the conclusion that the actual number of cases occurring must be a considerable one. The condition, according to reports, is usually observed in children under two years of age, and especially in artificially fed, poorly nourished infants, and in those with any difficulty in swallowing or breathing. The history of nasal discharge, coughing spells or asthmatic attacks frequently follows that of periodic instillations of oil into the nostrils.

These patients usually show the clinical signs and symptoms of a low-grade pneumonia, and present an x-ray picture that shows a shadow along the sternal border of the pulmonary fields. At autopsy the tissues show a foreign-body reaction with secondary bacterial invasion, and large amounts of oil are often found in the lungs. Organic oils, such as codliver oil and cream, usually

cause a different reaction—an acute pneumonia. As these fats are largely absorbable, chronic sequelae are less liable to occur.

The insidious danger of lipid pneumonia calls to mind the acute inhalation pneumonias that occurred a few years ago and were due to babies being allowed to play with dusting-powder cans with removable caps.

OBITUARY

THOMAS BARNES FUTCHER

1871-1938

In the death of Dr. Futcher, February 25, 1938, medicine in America loses one of her outstanding disciples. Death came to him suddenly, while he was making his rounds at the Johns Hopkins Hospital, from coronary thrombosis, at the age of sixty-seven.

Born in St. Thomas, Ontario, January 1, 1871, Futcher served as a house officer at the Toronto General Hospital in 1893-1894. There he came under the eye of Dr. James E. Graham, the professor of medicine, who was on the lookout for promising young men to send to the Johns Hopkins Hospital for further training under Dr. William Osler. Futcher came to Baltimore the same year and spent the summer as resident physician to the Garrett Children's Hospital at Mount Airy, Maryland, joining Dr. Osler's staff in September. He passed through the grades from assistant resident physician up to resident physician, a post which he held from 1898 to 1901. During this period he helped the late Dr. Thayer organize the first year of clinical teaching at the Johns Hopkins University School of Medicine in the winter of 1895-1896. With the clinical laboratory started in 1896, Futcher was put in charge. That year he organized and conducted the first course of systematic instruction in clinical pathology to be given in the country, if not in the world. As a part of this admirable course Futcher carefully prepared an excellent series of lectures. For this pioneer work he has never received the credit he deserves. He was one of the five first assistants trained by Osler, two having preceded him, Laffleur and Thayer, and two coming after him, McCrae and Cole. Following his resident service he became a visiting physician to the Johns Hopkins Hospital.

His relation with Osler was a very close one. When Dr. Thayer married, he left the other two "latchkeys," Jacobs and Cushing, at 3 West Franklin Street and Futcher took Thayer's place.

His widow, two sons, and a daughter survive him

MISCELLANY

CONNECTICUT NEWS

NEUROPSYCHIATRIC INSTITUTE INSTALLS LATEST DEVELOPMENT OF SCIENCE

A new Inductopyrexia, the latest contribution of science to the so-called fever treatment of certain types of diseases, has been installed at the Neuropsychiatric Institute of the Hartford Retreat. It will be used in the treatment of tabes, general paresis and other central nervous-system diseases of similar etiology This machine is the first of its kind to be installed in Connecticut and one of the first in this section of the country

ST FRANCIS HOSPITAL, HARTFORD

At the annual meeting of St. Francis Hospital in January, Dr James F Lynch was re-elected president of the medical staff for a third term. Five new directors were named to fill five vacancies caused by death during the year Dr Michael J Morrissey is one of the new directors. Among the changes and appointments in the staff positions were the following Dr N Herbert Bailey, changed from attending obstetrician to consulting obstetrician, Dr Richard C. Buckley, transferred from attending surgeon to neurosurgeon, Dr George E. Cogan, transferred from associate obstetrician to attending obstetrician, Dr Charles W O'Neil, elected assistant dermatologist Dr John F McGrath, elected assistant surgeon, Dr Martin P McCue, elected assistant physician, Dr David Gaberman, elected assistant pediatricist, Dr Joseph G Urrichio, elected clinical associate.

St. Francis Hospital was visited by fire near noon on February 3 when what bade fair to be a serious blaze in the Nurses Home was brought under control through the efficient work of the Fire Department. Three alarms were sounded in quick succession. Twenty six sleeping nurses were roused and led to safety The cost of repairing the damage will be \$7,000

HARTFORD BOARD OF HEALTH

Dr George E Cogan was re-elected president of the Hartford Board of Health at its annual meeting in January Dr Charles W Daly and Dr Cogan were appointed to the Committee on Communicable Diseases and Laboratory, Dr Cogan to the Committee on Finance and Personnel, and Dr Daly to the Committee on Public Health Nursing and Child Hygiene. A proposal was made that the city offer medical examinations to all persons connected with the handling of food in public eating places This will be discussed with the Hartford Medical Society The secretary announced that deaths in Hartford resulting from automobile accidents last year reached the low est figure since 1914

NEW INFIRMARY FOR LAUREL HEIGHTS TUBERCULOSIS SANATORIUM

A new seven story infirmary housing 140 patients and costing \$400,000 is to be built in the near future by the State Department of Public Works at Laurel Heights Tuberculosis Sanatorium in Shelton. Plans have been drawn and bids will be received in March The infirmary building will be located on the hillside, commanding a beautiful view of the Housatonic Valley, and will be constructed of brick with limestone and granite trim It will house a central heating plant to service three buildings

PNEUMONIA SERUM AVAILABLE IN TWENTY-FOUR HOUR SERVICE

The State Department of Health now furnishes a complete, twenty four hour, pneumonia service every day in the year The department also has funds available through the United States Public Health Service not only for furnishing this laboratory service but also for providing type specific antipneumococcus serum for six types of pneumonia instead of only two as heretofore. The department will furnish the serum free to Connecticut citizens upon whom payment would work a financial hardship

HOSPITAL VS HEALTH INSURANCE

Dr James R. Miller, representing the Medical Information Bureau of the Hartford County and City medical societies, recently discussed hospital and health insurance before a lay audience in that city Dr Miller explained why organized medicine is opposed to paying for the care of the sick with tax funds. He also made very clear the difference between hospital and health insurance and set forth the chief objections to the latter The *Hartford Courant* commenting on Dr Miller's address, said "If all medical associations are facing the issue as energetically as Dr Miller says is true of the Connecticut House of Delegates and are seeking an honest solution to the problem, there will be no socialized medicine in this country"

CHILD-HEALTH PROBLEMS DISCUSSED

Several eminent speakers took part in the program of the School Health Education Conference held in Hartford on January 18 Dr William W Bauer, director of the Bureau of Health and Instruction of the American Medical Association, and Dr Haven Emerson, of the College of Physicians and Surgeons, New York City, were most widely known.

puise rose to 132 during delivery but at the end of an hour had dropped to 88. No transfusion was considered necessary. The baby died about 10:56 p. m.

No laboratory work was performed on this case previous to delivery. The patient's convalescence was normal. At her discharge examination on the fourteenth day her red-blood-cell count was 4,200,000 and the hemoglobin 70 per cent. The cervix showed a slight bilateral laceration and the uterus was in third-degree retroversion, but was easily replaced in anterior position.

It is interesting to note how quickly after the initial hemorrhage a diagnosis was made and proper treatment under way. The initial hemorrhage occurred at 12:30 p. m., examination had been made and a bag inserted at 2:20 p. m. It would have been wise to have had a red count and hemoglobin made on this patient upon her arrival at the hospital, also there is no mention in the record that any attempt was made to procure a compatible donor. This routine is always a conservative procedure.

Any baby at thirty weeks has only a fifty per cent chance of living. It is quite likely that the laceration of the placenta causing initial hemorrhage and the use of the bag which may well have interfered with the baby's circulation during or lessened the chances of this premature child's survival. It is unlikely that the delivery of a child weighing 3 lb., 9 oz. through a cervix which has filled a Voorhees bag No. 5 would have harmed the infant in any way. It is possible that a Brax-Hicks slow extraction of the child after the insertion of the bag would have been more conservative. In this procedure the child's life is definitely disregarded. On the other hand, there is no question if the operator could in any way be credited for delivering this child through a cervix dilated as much as it must have been. This patient had previously had two full-term normal deliveries.

ANNUAL DIRECTORY

Under the provisions of the By-Laws the Council has ordered the publication of the Annual Directory of Officers and Fellows of the Society as of February 15, 1938. Return postcards are being sent to all Fellows of the Society, whose dues are informing them that they are entitled to a copy of the Directory and asking them to indicate whether they wish to receive it.

In order to save time the return postcard is addressed to the Boston Mailing Company, 394 Atlantic Avenue, Boston, Massachusetts.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 21.

BARNSTABLE

Sunday, March 27, at 4:00 p. m., at the Cape Cod Hospital, Hyannis. Subject: Early Syphilis. Instructor: C. Guy Lane. John I. B. Vail, *Chairman*.

BERKSHIRE

Thursday, March 24, at 4:30 p. m., at the House of Mercy Hospital, Pittsfield. Subject: Rheumatic Infection, Rheumatic Heart Disease. Instructor: T. Duckett Jones. Melvin H. Walker, Jr., *Chairman*.

BRISTOL SOUTH (Fall River Section)

Monday, March 21, at 4:30 p. m., at the Union Hospital, Fall River. Subject: Treatment of Burns. Instructor: Henry W. Hudson, Jr. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*.

ESSEX NORTH

Friday, March 25, at 4:00 p. m., at the Lawrence General Hospital, Lawrence. Subject: Treatment of Burns. Instructor: Henry W. Hudson, Jr. John Parr, *Chairman*.

FRANKLIN

Wednesday, March 23, at 8:00 p. m., at the Franklin County Hospital, Greenfield. Subject: Some Complications of Labor Analgesics in Labor. Instructor: James C. Janney. Halbert G. Stebbins, *Chairman*.

HAMPDEN

Thursday, March 24, at 4:00 p. m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p. m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject: Pneumococcus Pneumonia and Serum Therapy. Instructor: Frederick T. Lord. George D. Henderson and George L. Schadt, *Chairmen*.

HAMPSHIRE

Wednesday, March 23, at 4:15 p. m., in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject: Differential Diagnosis and Treatment of Scarlet Fever. Instructor: Edwin H. Place. Warren P. Cordes, *Chairman*.

MIDDLESEX EAST

Tuesday, March 22, at 4:00 p. m., at the Melrose Hospital, Melrose. Subject: Puerperal Sepsis. Instructor: Thomas R. Goethals. Joseph H. Fay, *Chairman*.

MIDDLESEX SOUTH

Wednesday, March 23, at 4:00 p. m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject: Bleeding in the Last Trimester of Pregnancy. Instructor: John Rock. Edmund H. Robbins, *Chairman*.

Health of the State Legislature will probably favorably report a bill for annual registration this coming week.

The present laws read that any physician opening an office must within two weeks present credentials and sign statements with the city or town clerk, and said clerk must transmit copy of the statement to the State Board of Registration within twenty four hours and both are subject to fines for not so doing. Why inconvenience 7000 and more physicians until reasonable attempts have been made to enforce this and other rigorous existing laws? How do lapses affect malpractice insurance? Would the medical profession continue to be ruggedly independent? Many other questions might be asked.

RICHARD DUTTON, M.D.

33 Avon Street, Wakefield

REPORT OF MEETING

EASTERN HAMPDEN MEDICAL ASSOCIATION

The first monthly meeting of the fifty-eighth annual session of the Eastern Hampden Medical Association was held on Wednesday evening, March 9, at the Oaks Hotel, Springfield.

Dr. Michael J. Krnichuck, of South Hadley Falls, read the paper of the evening on 'The Clinical Significance of the Cerebrospinal Fluid' which was discussed by Drs. Dickson, Boyd and Schamlian.

Case reports were rendered by Dr. R. E. Dickson, of Holyoke, and Dr. Roberta E. Neill of Springfield.

While the Society meets every month on the Thursday nearest the full moon, it was voted to change the next meeting date to Wednesday, April 13, because of conflict with the postgraduate extension lecture on Thursday, April 14.

J. JOSEPH KLAR, *Secretary-Treasurer*

NOTICES

COURSE IN OCCUPATIONAL DERMATOSES

During May, 1938, a course in Occupational Dermatoses will be given under the auspices of the Harvard School of Public Health. Lectures will be given on the clinical manifestations, etiological factors, diagnosis, treatment, insurance and legal aspects, and so forth. Clinics will be held at the Massachusetts General Hospital, and at the various insurance companies. Visits to some of the more important factories will be arranged, so that students may study industrial processes and preventive measures. The number will be limited to ten. Further information and registration blanks may be obtained from the Dean of Harvard School of Public Health, 25 Shattuck Street, Boston, Mass.

DR. CRUCHET TO HOLD CLINIC

Dr. Rene Cruchet, professor of medicine, Bordeaux, France, will hold a clinic in the Evans Memorial Auditorium, 78 East Concord Street, Boston, on Monday, March 21, at 12 o'clock noon. His subject will be Morvan's Disease in Childhood.

SPRINGFIELD DISTRICT TEACHING CLINICS

In conjunction with the state wide movement to publicize the work of the cancer clinics, a teaching clinic will be held for the members of the medical profession of the Springfield district at the Springfield Hospital on April 1 at four in the afternoon. The guest speaker, Ashley W.

Oughterson, M.D., Associate Professor of Surgery at Yale University School of Medicine, will conduct the clinic. Also, on Friday, April 5, at four in the afternoon at the Academy of Medicine in Springfield, Dr. C. C. Little of the Roscoe B. Jackson Memorial Laboratory of Bar Harbor, Maine, will be the guest speaker and his subject 'Some Recent Advances in Cancer Research'. All local members of the medical profession are cordially invited to attend both these exercises.

COURSE FOR MEDICAL RESERVE OFFICERS OF THE UNITED STATES ARMY

The Harvard Medical School, Courses for Graduates offers a course with special reference to traumatic and military surgery and medicine. The course is limited to officers holding a commission in the Medical Reserve Corps of the United States Army and will be given for two weeks beginning June 1. Attendance at this course will be given inactive duty credit by the War Department.

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS

Of special interest to every physician and surgeon of this country is the program of the American Association of Industrial Physicians and Surgeons 1938 meeting.

To broaden the interest in industrial medicine to the end of minimizing the morbidity and mortality of working people, reducing accidents and the number of deaths or cripples resulting therefrom, removing the hazards of occupational diseases, and keeping more people on their jobs in healthy condition—all these are naturally of vital interest to the physician or surgeon in general practice.

Acquaintance with industrial medical problems such as these is increasingly important to every physician and surgeon whether he be exclusively in private practice or identified, in whatever relation, with industrial medicine. Thus he will do well to mark on his calendar June 6, 7, 8 and 9, for this meeting of the American Association of Industrial Physicians and Surgeons, which will be held concurrently with the Midwest Conference on Occupational Diseases at the Palmer House in Chicago. The field of industrial medical practice is increasingly prolific of broader opportunities and closer co-operation with physicians and surgeons in every specialty and in every locality.

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held on Monday, March 21, at 11:30 a.m. in the Andrew Carney Assembly Hall.

PROGRAM

Case Report: Lymphatic Leukemia. Dr. F. Ciampi. Pathology Exhibit.

Address: Coccydynia. Dr. John S. Kelley. Discussion: Dr. H. G. Lee, Dr. J. L. Doherty and Dr. M. V. Norton.

R. J. HEFFERNAN, M.D., *Secretary*

BOSTON MEDICAL HISTORY CLUB

Under the auspices of the Boston Medical History Club, Dr. W. Richard Ohler will speak on 'The Development of Our Knowledge of the Kidneys and Their Diseases' at the Boston Medical Library, 8 Fenway, Boston. The meeting will be held on Monday, March 21, at 8:15 p.m.

BENJAMIN SPECTOR, M.D., *Secretary*

MT SINAI HOSPITAL STAFF APPOINTMENTS

Mt. Sinai Hospital, Hartford, has announced its staff appointments for the year. The chief physicians are D. N. Shulman, Peter Steincrohn, and Samuel Donner. The chief surgeons are William Lechner, Louis Antupit and Joseph Heyman.

MEDICAL SOCIETY HONORS DR. STEINER

About fifty friends of Dr. Walter R. Steiner were present at a dinner in his honor at the Hartford Club on February 7. After the dinner Dr. Archibald Malloch, librarian of the New York Academy of Medicine, delivered an address before the Hartford Medical Society on "Medical Libraries." Dr. Malloch paid fitting tribute to Dr. Steiner, who has served the Society as its librarian for 35 years and for whom the Society recently named its library of 20,000 volumes. A portrait of Dr. Steiner, the gift of a friend and patient, was presented to the Society and unveiled before the assembled group of members. The fitting remarks of the president, Dr. Edward J. Whalen, added greatly to the impressiveness of the occasion.

FAIRFIELD COUNTY MEDICAL ASSOCIATION

In co-operation with the local medical societies the Fairfield County Medical Association has been conducting a series of monthly meetings in different cities of the county. On January 11 at Greenwich, Dr. George Blumer, of Yale University School of Medicine, gave a very clear and instructive talk on "Subacute Bacterial Endocarditis." On February 9, at the Norwalk Hospital, Dr. Harold M. Marvin, of New Haven, discussed "Myocardial Failure." The remainder of the program follows:

March 8, 8:30 p. m., Stamford Hall. Speaker, Dr. Clarence L. Robbins, New Haven. Subject, "Edema: Its differentiation and treatment."

April 12, 3:30 p. m., Stratfield Hotel, Bridgeport. Speaker, Dr. Harry Zimmerman, New Haven. Subject, "Vascular Diseases of the Central Nervous System."

May 12, 9 p. m., Hotel Green, Danbury. Speaker, Dr. Ashley Oughterson, New Haven. Subject, "Peripheral Vascular Disease: Its conservative treatment."

DEATHS

AXTELLE—JOHN FRANK AXTELLE, M.D., aged 83, formerly a practitioner in Hartford, died at the Masonic Home in Wallingford on February 9.

CARVER—JOHN PRESTON CARVER, M.D., aged 66, medical examiner for twenty years and general practitioner in medicine in Simsbury since 1902, died at his home, February 4, after an illness of three months. Death was said to have been due to heart disease. A native of Pelham, Massachusetts, he was the son of the late Freeman C. and Almira (Thayer) Carver. He spent most of his youth in Northampton, Massachusetts, and in 1896 was graduated from the Albany Medical College. After a postgraduate course at the New York College of Physicians and Surgeons he began practice in New Hartford and came to Simsbury in 1902. He was physician for Westminster School. His practice extended to nearby communities, and for many years he made calls, day and night, throughout the countryside. In 1898 he married Helen E. Eno, of Simsbury. Besides his widow, he has left three daughters, Mrs. Thomas Whitman, Mrs. Esther C. Standish and Miss Martha Carver, all of Simsbury, two grandchildren, a sister, Mrs. Cora Carver Larimer, and a half brother, Richard Carver, of Northampton.

KELLOGG—CLIFFORD WALCOTT KELLOGG, M.D., aged 77, well known physician, died of pneumonia on January 31 at Middlesex Hospital, Middletown, where he was taken after a two weeks' illness. Born in South Amherst, Mass., a son of the late Beulah H. and Elizabeth (Walcott) Kellogg, he moved to Hartford when a boy. He was graduated from Yale University and entered Yale University School of Medicine, graduating at the head of his class. For a year he remained as a lecturer at the school and then interned at the New Haven Hospital, where he became superintendent. His wife was the former Edith Raymond, of New Canaan, who was superintendent of nurses at the hospital when Dr. Kellogg met her. Later Dr. Kellogg entered general practice in New Haven, which he continued for a few years, and then moved to Higganum where he practiced medicine for eighteen years. In 1917 he opened an office on Washington Street, Middletown, continuing practice there until about two years ago when he retired to his home in Higganum.

Dr. Kellogg was well known for his musical and inventive talents. He wrote several Yale songs, the most popular of which was "Yale Blue Forever." He contributed many articles to medical journals and was a member of the Middletown Medical Society and the American Medical Association. Dr. Kellogg leaves four daughters, Mrs. R. L. Hayden, of Haddam, and Mrs. Patrick Doyle, Miss Margaret and Miss Dorothy Kellogg, all of Higganum, three grandchildren, and two sisters, Mrs. Louise Thayer and Mrs. Frank Brandell, both of Northampton, Massachusetts.

WEIR—LOREN RAY WEIR, M.D., aged 54, eye, ear, nose and throat specialist in New Britain during the past fifteen years, died suddenly at his home, February 10, of heart disease. Dr. Weir was born in Burnside, Illinois, and after graduating from high school entered the Hahnemann Medical School in Kansas City, Missouri, entering the practice of medicine in Lathrop, Missouri, after his graduation. He served during the World War as a lieutenant in the U. S. Army Medical Corps. In 1920 he took up a specialized study of eye, ear, nose and throat ailments, going to New Britain to specialize in 1923. He was on the staff of New Britain General Hospital, and a member of the city and county medical societies and of the South Congregational Church. He was a past master of Lathrop Lodge, A. F. & A. M., and a member of the Commandery and the Mola Shrine of St. Joseph, Missouri. He is survived by his widow, Mrs. Mae A. Weir, two brothers, Dr. C. E. Weir, of Abingdon, Illinois, and Hugh L. Weir, of Galesburg, Illinois, two sisters, Mrs. George Aldrich, of Roseville, Illinois, and Mrs. Ernest Wilke, of Charles City, Iowa, and two half brothers, Bernard and Forest Weir.

CORRESPONDENCE

THE PROPOSED BILL FOR ANNUAL REGISTRATION OF PHYSICIANS IN MASSACHUSETTS

To the Editor—In 1936, 1937 and 1938 the State Board of Registration has made determined drives to compel the medical profession to "trade in" its permanent right to practice medicine in Massachusetts for an annual permit with varying and probably increasing restrictions. The Council of the Massachusetts Medical Society has each year emphatically opposed such proposed legislation. It is surprising, therefore, to learn that the Committee on Public

BOOK REVIEWS

Cho Medica xix Pathology E. B. Krumbhaar 206 pp
New York Paul B Hoeber, Inc., 1937 \$2.00

This volume of *Cho Medica*, a series of primers on the history of medicine, concerns the history of pathology. There are eight chapters, an epilogue, two appendices, and a chronologic list of pathological milestones. The scope of the book is indicated by the titles of the eight chapters, which are as follows: 'Primitive, Classical and Medieval Concepts Pathology of Antiquity', 'Theories of the Nature of Disease', 'The Rise of Anatomic Concepts in Disease', 'Systematized Gross Pathologic Anatomy', 'Pathologic Anatomy of the Tissues and Precellular Pathology', 'Cellular Pathology', 'Integrated Pathology Structural Functional, Chemical, Experimental and Clinical Methods of Approach', 'Special Concepts Inflammation, Cancer

The author, a professor of pathology of great distinction and noted for his interest in the history of medicine, has achieved an admirable performance, and it is quite clear that he has selected his material wisely from a vast fund of knowledge. The reviewer's main criticism is that the limitation imposed by space has compelled the author to write with great economy of words, nevertheless the volume is very readable. The logical presentation and wise selection of material give the reader an easily remembered knowledge of the development of pathology, concurrently with the development of rational medicine. In spite of the condensation of material and inhibition of the author's usual flowing style, the effect of sequence is strong. The chapter "Integrated Pathology" could well have been em-

phasized at the expense of the chapter on inflammation and cancer

There will be many dissenters to Dr Krumbhaar's list of pathological milestones. In the opinion of the reviewer he has included among the worthy a few of lesser merit. A short bibliography will serve to direct the reading of persons whose interest in medical history goes beyond the scope of this volume. The reviewer highly recommends it as collateral reading for medical students in the study of pathology and is convinced that the booklet will receive the grateful reception that it deserves.

A Textbook of Medicine By American Authors. Edited by Russell L. Cecil. Fourth edition, revised and entirely reset. 1614 pp Philadelphia and London W B Saunders Company, 1937 \$9.00

This textbook of medicine needs little description because of the familiarity of students and physicians with the previous editions, which have comprised a systematic arrangement of contributions by a group of men who are masters of their particular subjects. The increase in medical knowledge since 1933 clearly justifies a new edition of this book. To a certain extent the present revision represents a new deal in that younger men have revised many of the articles on old subjects, these are consistent with the high standard of the text. Most of the 130 contributors are members of university medical schools and have presented their material in a form especially suitable for medical students. A number of entirely new topics has been introduced lymphogranuloma inguinale, several new virus infections, pneumonia in childhood, staphylococcal infections, meningococcal sepsis, spontaneous hypoglycemia, the nephroses, classification of diseases of the heart, and diseases of the peripheral vessels. The arrangement of material has not been changed to any considerable extent, though in the section on infectious diseases the various conditions have been grouped under such headings as virus diseases, streptococcal infections, bacillary diseases, and so forth. The description of any one condition is necessarily brief. Nevertheless, well-chosen references at the end of each article provide suggestions for further reading, including articles on treatment. Thus the volume, though primarily a textbook for students, should be useful to the practitioner for its succinct descriptions of conditions with which he may not happen to be familiar and for its convenient references to outstanding articles in the literature.

Diseases of the Heart Described for practitioners and students Sir Thomas Lewis. Second edition. 297 pp New York The Macmillan Company, 1937 \$3.50

The first edition of this book was published in 1933. The new edition has very few changes. These are as follows: the section on diuretics now includes salyrgan, and theophylline has been substituted for theobromine, the diuse of strophanthus is recommended, the section on constrictive pericarditis has been rewritten and surgical treatment given its proper place, more interest is shown in the removal of sympathetic ganglia in cases of angina pectoris, the carotid sinus is included under the causes of syncope, the prognosis in coronary thrombosis has been made more hopeful, there are a few minor changes in the treatment of essential hypertension, finally, a little more credit is given to the action of digitalis in cases of chronic congestion that present regular heart action, and that have been treated with all the usual methods without success." The 1933 edition said these cases *seem* to respond to full doses of digitalis." The new edition says

SULFANILAMIDE A REVIEW

MAURICE A. SCHNITZER, M.D.*

BOSTON

IT is now approximately three years since the new chemotherapeutic agent, prontosil, for the treatment of infections due to streptococci was presented to the medical profession. Whenever a new measure is introduced in therapeutics it is appropriate, after the accumulation of sufficient data, to review the evidence for and against its use, to learn especially the best method of application, and, most of all, to ascertain its limitations. In the case of sulfanilamide, the active principle derived from prontosil, this is particularly true because of the immediate enthusiasm with which it has been accepted.

Published articles on prontosil and its derivatives, including sulfanilamide, have been so numerous as to make it difficult to keep abreast of the subject. In fact, since Domagk's¹ original article, which appeared February 15, 1935, and which introduced prontosil for the treatment of hemolytic streptococcal infections in mice, two hundred and fifteen articles† on the subject had been published up to November 1, 1937. To be sure, it is still too early to evaluate all the possibilities and potentialities of this drug and to draw any far-reaching conclusions. Yet enough has been learned about its value in the treatment of certain conditions, the diseases in which its use has been unsuccessful and its definite toxic effects to warrant a brief résumé.

CHEMISTRY

The azo dyes, from which prontosil and sulfanilamide are derived, have been utilized in the textile industry for the past twenty-five years as dyes for cotton, wool and silk. In this industry it has been known for a long time that azo dyes form an intimate combination with the cellular protein. While studying this interesting phenomenon, Eisenberg² tested the behavior of one of these dyes, chrysoidin, on bacteria *in vitro*, and found it to have a strong bactericidal action. It was thus in-

troduced as a chemotherapeutic agent, and subsequently various other azo compounds, trypan blue and so forth, were tried, particularly as urinary disinfectants, but with equivocal therapeutic results.

In 1932 Meitzsch and Klarer, while investigating chrysoidin, synthesized a chloride of the sulfonamide of chrysoidin, producing 4-sulfamido-2,4-diaminoazobenzene hydrochloride.‡ This was a red crystalline powder, slightly soluble in water, with a melting point of from 247 to 251°C. It was this substance that Domagk demonstrated in 1935 as exerting a protective action when given intravenously to mice infected with streptococci. He called the substance prontosil.

Unfortunately there are three substances with the name prontosil, and this has caused much confusion in the medical literature. The first is the monohydrochloride synthesized by Meitzsch and Klarer. The second is the dihydrochloride (4-sulfamido-2,4-diaminoazobenzene dihydrochloride) which is slightly more soluble in water and is just as effective. The dihydrochloride is also known as Prontosil Flavum, Prontosil Tablets and Rubiazol (a French preparation). The third prontosil is the disodium sulfonate salt (4-sulfamidobenzene-2-azo-1-hydroxy-7-acetyl-amino-naphthalene-3,6-disodium sulfonate). The dihydrochloride salt is commonly used in Europe, the red prontosil solution employed in this country is the disodium salt in 25 per cent solution. This is also known as Prontosil Red, Prontosil Soluble, Prontosil S and Prontosil Solution. There was immediate and widespread interest in the use of these substances in both human and experimental infections caused by streptococci. In general the results were favorable.

The next important development came from Tréfouël, Tréfouël, Nitti and Bovet.³ In their experimental work with prontosil they demonstrated that the azo linkage was not necessary in the molecule, but that the substance probably responsible for the

they "respond to full doses of digitalis" No changes have been made in the fundamental setup of the work and the paging throughout remains the same.

The book was written for the medical student who knows too much of the electrocardiogram and modern cardiologic terminology and not enough of symptoms and signs and the working classification of heart disease. It was meant to appeal likewise to the practitioner who knows too little of the modern concepts. For both these groups the book has much to offer, and by many it is considered ideal for their needs.

The American cardiologists, however, are not satisfied because they believe that too much emphasis is placed on congestion of the systemic veins and obvious cardiac failure with no acceptance of what they believe to be the fundamental concept of left ventricular failure without the accompanying failure of the right heart. To them this is a fundamental error both from the physiologic and the practical standpoint. They have long maintained that the practitioner should be taught to recognize left ventricular failure and treat patients effectively at this stage, and often prevent the failure of the right heart. In the present work the emphasis on congestion of the cervical veins is so great that the practitioner is apt to consider it the one thing for which he should look, whereas to the American cardiologist this is a late manifestation of disease and not an early one.

The second criticism of the original edition was that it gave too little place to the use of digitalis in cases where the cardiac rhythm was regular. As noted above, this criticism will be slightly modified by the changes in the new edition, but there is still no mention of its use in left ventricular failure.

So in spite of grateful appreciation for the simplified handling of the details of modern cardiologic lore, and admiration for the authors' remarkable clarity in the presentation of his conclusions, the majority of American cardiologists will continue to recommend the book with reservations.

Diseases of the Nervous System in Infancy, Childhood and Adolescence Frank R Ford. 953 pp Springfield and Baltimore Charles C Thomas, 1937 \$8.50

This textbook about the diseases of the nervous system in infancy, childhood and adolescence has all the advantages and equally all the disadvantages of any textbook. In addition, it has a distinctly local, not to say provincial, flavor. This is perhaps inherent in any textbook that has its source in a large teaching center of medicine, and provided that the academic trends there are good and that the book mirrors those trends correctly, it is a useful attribute.

Rightly or wrongly the Johns Hopkins group is credited with a tendency toward the investigation of and interest in the unusual and bizarre in medicine. Certainly the detailed and up-to-date consideration of the more uncommon types of nervous diseases in this book and the corresponding sketchy and antiquated presentation of the more common everyday analogous abnormalities bear out this belief. As is to be expected, the author emphasizes the congenital origin of central nervous-system changes wherever possible and has plumped wholeheartedly for the Hopkins school of thought in regard to the surgical lesions. The section on brain tumors is to be especially commended even if nothing more has been done than the simplified presentation of the problem. Other sections, of more interest perhaps to the general practitioner, do not conform to this high standard. In speaking of brain abscess, for example, the statement is made on page 400

that in acute abscesses which are not encapsulated, no treatment is of any avail." King's brilliant work in the therapy of this encephalitic type of abscess cannot be dismissed in such a summary fashion without critical comment. So, too, in the section on bladder physiology no mention is made or reference given to Denny Brown and Robertson's classical work on this organ or to Munro's studies of normal and abnormal cystometrograms. Tidal drainage is not referred to throughout the book. The making of electromyograms in the differential diagnosis of many of the strictly neuromuscular conditions is omitted, recent work on the carotid sinus reflex and on subdural hematomas has been overlooked, and finally, the important modern conception of migraine as a member of the so-called epileptic syndrome has been entirely neglected. As in many other sections but particularly in that devoted to 'Epilepsy and the Paroxysmal Disorders,' the references as well as the text are already out of date. The reviewer classified the references under all sections on epilepsy and found that there were only one 1937, one 1934, two 1932, and six 1931 references. Including 1930 and going as far back as 1901, however, there were 63 references. No one would seriously contend that significant work on this convulsive state all but came to an end after 1930.

On the whole, however, the book will serve its purpose in the same way that any textbook does that is, as a starting point from which the reader can, if he likes, go farther in his investigations, as a place to find out the name of the strange diseases that one sees once in a lifetime, and as an attractively written and presented exposition of the Hopkins' school of thought. In the next edition, however, it is to be hoped that the author will bring the sections dealing with the commoner central nervous-system affections of infancy and childhood up to date and make them representative of a wider point of view.

Malnutrition the Medical Octopus John Preston Sutherland 368 pp Boston Meador Publishing Company, 1937 \$3.00

This volume presents the convictions of a well known former member of the Faculty of the Boston University School of Medicine who has made a careful study of the problems incident to malnutrition, together with many quotations which are used to fortify the claims set forth. Beginning with fetal life the contention is made that the subsequent health conditions of the individual depend to a large degree on the mother's dietary habits, and in the succeeding chapters the author places the responsibility for much of the ill health and susceptibility to diseases on the use of cows' milk, meat, white flour and granulated sugar.

With the elimination of these condemned articles from the diet and the use of fruits, nuts, berries, unprocessed cereals and a wide range of vegetables one will be able to do more and better work, live longer and be less likely to contract disease, citing the author's experience along this line for thirty-eight years as evidence.

The well known facts relating to beriberi and pellagra, as deficiency diseases, lead to the assumption that cancer may be included in this category by the author.

At the end of the book there is presented a complete list of approved foods which may be a guide to those who share the author's views.

The opinions expressed in this volume are clearly and forcefully presented, but, in many respects, are at variance with the generally accepted views of the medical profession.

SULFANILAMIDE A REVIEW

MAURICE A. SCHNITKER, M.D.*

BOSTON

IT is now approximately three years since the new chemotherapeutic agent, prontosil, for the treatment of infections due to streptococci was presented to the medical profession. Whenever a new measure is introduced in therapeutics it is appropriate, after the accumulation of sufficient data, to review the evidence for and against its use, to learn especially the best method of application, and, most of all, to ascertain its limitations. In the case of sulfanilamide, the active principle derived from prontosil, this is particularly true because of the immediate enthusiasm with which it has been accepted.

Published articles on prontosil and its derivatives, including sulfanilamide, have been so numerous as to make it difficult to keep abreast of the subject. In fact, since Domagk's¹ original article, which appeared February 15, 1935, and which introduced prontosil for the treatment of hemolytic streptococcal infections in mice, two hundred and fifteen articles² on the subject had been published up to November 1, 1937. To be sure, it is still too early to evaluate all the possibilities and potentialities of this drug and to draw any far-reaching conclusions. Yet enough has been learned about its value in the treatment of certain conditions, the diseases in which its use has been unsuccessful and its definite toxic effects to warrant a brief résumé.

CHEMISTRY

The azo dyes, from which prontosil and sulfanilamide are derived, have been utilized in the textile industry for the past twenty-five years as dyes for cotton, wool and silk. In this industry it has been known for a long time that azo dyes form an intimate combination with the cellular protein. While studying this interesting phenomenon, Eisenberg³ tested the behavior of one of these dyes, chrysoidin, on bacteria *in vitro*, and found it to have a strong bactericidal action. It was thus in-

troduced as a chemotherapeutic agent, and subsequently various other azo compounds, trypan blue and so forth, were tried, particularly as urinary disinfectants, but with equivocal therapeutic results.

In 1932 Meitzsch and Klarer, while investigating chrysoidin, synthesized a chloride of the sulfonamide of chrysoidin, producing 4-sulfamido-2,4-diaminoazobenzene hydrochloride.⁴ This was a red crystalline powder, slightly soluble in water, with a melting point of from 247 to 251°C. It was this substance that Domagk demonstrated in 1935 as exerting a protective action when given intravenously to mice infected with streptococci. He called the substance prontosil.

Unfortunately there are three substances with the name prontosil, and this has caused much confusion in the medical literature. The first is the monohydrochloride synthesized by Meitzsch and Klarer. The second is the dihydrochloride (4-sulfamido-2,4-diaminoazobenzene dihydrochloride) which is slightly more soluble in water and is just as effective. The dihydrochloride is also known as Prontosil Flavum, Prontosil Tablets and Rubiazol (a French preparation). The third prontosil is the disodium sulfonate salt (4-sulfamidobenzene-2-azo-1-hydroxy-7-acetyl-amino-naphthalene-3,6-disodium sulfonate). The dihydrochloride salt is commonly used in Europe, the red prontosil solution employed in this country is the disodium salt in 2.5 per cent solution. This is also known as Prontosil Red, Prontosil Soluble, Prontosil S and Prontosil Solution. There was immediate and widespread interest in the use of these substances in both human and experimental infections caused by streptococci. In general the results were favorable.

The next important development came from Tréfouël, Tréfouël, Nitu and Bovet.⁵ In their experimental work with prontosil they demonstrated that the azo linkage was not necessary in the molecule, but that the substance probably responsible for the

⁴Deutsches Reich Patent 607537 of Dec. 25, 1932 and additional patents, D. R. P. 610320 of Dec. 1, 1933 and D. R. P. 635701 of Apr. 19, 1934.

action of the chemical was para-aminobenzenesulfonamide. Shortly thereafter Colebrook, Buttle and O'Meara,⁴ and Fuller⁵ in England, and Bliss and Long⁶ in the United States demonstrated that prontosil is probably broken down to para-aminobenzenesulfonamide in the human organism. This is now considered the effective agent. This pertinent fact has prompted the Council of Pharmacy and Chemistry of the American Medical Association⁷ to accept para-aminobenzenesulfonamide as an active chemotherapeutic substance in the treatment of infections due to hemolytic streptococci. Because this and related compounds were appearing on the market under a great variety of different names, the council selected "sulfanilamide" as the accepted name.⁸

Sulfanilamide is also used under the nomenclature of Prontosil Album and Prontylin. It is a white crystalline substance, readily soluble in hot water, hot alcohol and cold acetone, only slightly soluble in cold water and cold alcohol, and insoluble in ether, benzene and chloroform. It is neutral to litmus in an aqueous solution. For clinical purposes sulfanilamide has the desirable qualities of being easily administered and absorbed, when given by mouth, and is relatively inexpensive and of low toxicity.

MODE OF ACTION

When sulfanilamide is administered to mice immediately after experimental infection, it has a protective action so long as the chemical is given. It may protect the animal from several thousand minimal lethal doses of streptococci. If administration of the drug is delayed for several hours, however, or if the treatment is stopped before the animal recovers, it invariably dies. This demonstrates a bacteriostatic (growth-arresting) effect on the organism, although the exact site and mode of action are still unknown. Such an effect on streptococci in vitro has been shown in many experiments. A strongly bactericidal (organism-destructive) action has not been demonstrated in vitro or in vivo, except perhaps in the urine. Bliss and Long⁹ believe that sulfanilamide acts by inhibiting the growth of hemolytic streptococci, perhaps injuring the organisms in such a way as to permit them to be phagocytosed by the white blood cells. Leukocytes are essential in the action of this drug, but whether its effects are primarily on the bacteria or on the white blood cells has not been determined.

Various other hypotheses have been advanced to explain the mode of action of sulfanilamide. These include injury to the capsule of the organism, inhibition of toxin formation and specific activation of the reticuloendothelial system. The protective

action of the blood following sulfanilamide administration may be supplemented by that of the tissues of the whole animal, as suggested by Colebrook, Buttle and O'Meara.⁴ This notion of body immunity as a factor is further suggested by recent observations that, while first infections of gonorrhea do not respond to the treatment, after an individual has had the disease for a time, good therapeutic results may be obtained.

EFFECTS ON BODY TISSUES

Until the accidental deaths caused in October, 1937, by sulfanilamide in diethylene glycol solution (Elixir of Sulfanilamide—Massengill), little study has been made of the organs of animals purposely killed by this drug. Hawking¹⁰ gave toxic doses of sulfanilamide to rabbits and cats, and in those that recovered he found no histologic changes in the liver, kidneys or other viscera. Those animals which died from very large doses showed slight degenerative changes in the central nervous system in the form of chromatolysis in neurons of the anterior columns of the spinal cord, and in some of the nerve cells of the cortex and midbrain. In mice, Hageman¹¹ found some hemosiderin deposition in the spleen and slightly increased eosinophilia in the bone marrow.

Sulfanilamide could not be blamed as the cause of death in the patients who died after taking Elixir of Sulfanilamide. Necropsies and animal experiments showed that the cause was the diethylene glycol used as a vehicle. In the control studies on this problem done by Cannon,¹² two dogs and four rats were given sulfanilamide alone to see whether any tissue changes occurred. One dog and none of the rats experienced toxic manifestations. Autopsy revealed slight microscopic changes in the kidneys, consisting of moderate fatty degeneration in some of the collecting tubules of the dogs, but minimal in the rats. The livers of both dogs and rats showed no hydropic degeneration and practically no fatty changes. Sufficient observations on the organs of patients dying after sulfanilamide had been administered have not appeared. Although many of the clinical results reported following sulfanilamide treatment have been striking, its effect on body tissues in terms of late pathologic changes caused by this drug remains for the future to disclose.

CLINICAL USE

At present the clinical use of sulfanilamide is necessarily almost wholly empirical because the site and exact mode of action are not known. In the human subject, by any route of administration, the drug is readily absorbed and quickly diffused through the tissues. In this respect it is

similar to alcohol and urea¹³ Because of its ready diffusibility it attains a wide distribution, having been found in the cerebrospinal fluid, pleural fluid, prostatic secretion, saliva, pancreatic juice and bile in concentrations slightly lower than that of blood. On the other hand, the heart muscle, skeletal muscle, liver, lung and spleen contain a concentration nearly equivalent to that of the blood, whereas the skin and brain contain less, and bone and fat only small amounts. This information has encouraged the use of the drug in practically all types of inflammation involving the above secretions and due to causes even far removed from the original intention, in other words, as a therapeutic agent in infections due to hemolytic streptococci. For clinical use, the Council of Pharmacy and Chemistry has accepted sulfanilamide only for the treatment of infections due to beta-hemolytic streptococci of Lancefield's serologic Group A, although it has been found to be effective against a few other organisms.⁷

Certain observations have been of the greatest importance in establishing a rational basis for the treatment of infected human subjects. Unless the illness is critical and treatment must therefore be begun promptly, it is advisable to isolate and identify the infecting organism first, and with it test the effect of the drug in vitro. The action of the drug is better in vivo than in vitro, particularly against virulent strains of hemolytic streptococci, consequently, if sulfanilamide is effective in vitro, good clinical results may be expected.¹⁴ Evidence for this is the fact that in beta-hemolytic streptococcal infections in human beings where treatment with sulfanilamide failed, subsequent in vitro experiments with the isolated organism have shown the drug to be ineffective as a bacteriostatic agent.

A level of from 7 to 10 mg of sulfanilamide per 100 cc. of blood is optimum in obtaining the desired therapeutic effect. Little may be expected if the blood level is less than 5 mg per cent. The rate of absorption of the drug from the gastrointestinal tract or from muscle is quite rapid, occurring within three to five hours. When given subcutaneously the dye may appear in the urine in fifteen minutes. Balance studies done on human subjects¹⁵ indicate considerable individual variation, but in general when the drug is given in divided doses it takes from two to three days to establish equilibrium between the amount ingested and the amount excreted, when it has been discontinued, it takes about the same length of time to free the organism of the chemical. With normal kidneys, the drug is excreted almost wholly in the urine. In the case of decreased renal function, urinary excretion is diminished, and continued administra-

tion of sulfanilamide results in its accumulation in the body. Furthermore, toxic effects are not uncommon. These principles are necessary guides in the use of sulfanilamide in the treatment of human infections.

Method of Determination in Blood and Urine The determination of the quantity of sulfanilamide in blood, urine and body fluids is advisable in every case where this drug is used. The method, originally devised by Marshall et al¹⁵ is simple enough for routine clinical use.

Procedure for Blood Two cubic centimeters of oxalated whole blood is measured into a flask and laked with 16 cc. of 0.05% aqueous solution of saponin. Shake and allow to stand for 2 minutes. Add 2 cc. of 20% trichloroacetic acid, shake, allow to stand 1 minute, and filter. Ten cubic centimeters of the filtrate is measured into a small flask and 1 cc. of 0.1% sodium nitrite solution that has been freshly prepared is added. Allow to stand 3 minutes, then add 5 cc. of a solution of dimethyl-alpha naphthalamine (1 cc. of concentrated dimethyl-alpha naphthalamine dissolved in 250 cc. of 95% of ethyl alcohol). The result will be a purplish red azo dye, the amount of color produced being directly proportional to the amount of sulfanilamide present in the fluid analyzed.¹⁶ Compare with standard.

Procedure for Urine Dilute 1 cc. of urine to a 60-cc. volume with distilled water. Measure 10 cc. into a flask and add 1 cc. of 20% trichloroacetic acid and 1 cc. of 0.1% sodium nitrite, and allow to stand for 3 minutes. Add 5 cc. dimethyl-alpha naphthalamine (1 cc. in 250 cc. of 95% of ethyl alcohol). After 10 minutes, compare with standard.

Standard Add 1 mg sulfanilamide to 18 cc. of 20% trichloroacetic acid and make to a volume of 100 cc. with distilled water. Treat 10 cc. of this solution exactly as outlined under blood. Place in a Duboscq colorimeter cup with vernier scale at 20 mm. and compare the unknown.

Calculation

$$\frac{20}{X} = \text{mg per cent sulfanilamide, where 'X'}$$

is the reading of the unknown.

If the solution of blood or urine contains too large a quantity of chromogen for comparison, the appropriate dilution or filtrate can be made.

Oral Administration The method of choice in the administration of sulfanilamide is by mouth. With this method it is usually easiest to maintain the blood level at from 7 to 10 mg per cent. Sulfanilamide, or prontosil, is put up in tablet form, 0.3 gm (5 gr) and 0.5 gm (7.5 gr), mixed with an excipient for oral use. The daily dose for the average human adult has been expressed in terms of body weight, 0.1 gm per kilogram or 1 gm for each 20 lb, but regardless of weight, the total dose per day should not exceed 5 gm., as toxic effects may result. In children, to maintain the optimum blood level 0.15 gm per kilogram of

action of the chemical was para-aminobenzenesulfonamide. Shortly thereafter Colebrook, Buttle and O'Meara,⁴ and Fuller⁵ in England, and Bliss and Long⁶ in the United States demonstrated that prontosil is probably broken down to para-aminobenzenesulfonamide in the human organism. This is now considered the effective agent. This pertinent fact has prompted the Council of Pharmacy and Chemistry of the American Medical Association⁷ to accept para-aminobenzenesulfonamide as an active chemotherapeutic substance in the treatment of infections due to hemolytic streptococci. Because this and related compounds were appearing on the market under a great variety of different names, the council selected "sulfanilamide" as the accepted name.⁸

Sulfanilamide is also used under the nomenclature of Prontosil Album and Prontylin. It is a white crystalline substance, readily soluble in hot water, hot alcohol and cold acetone, only slightly soluble in cold water and cold alcohol, and insoluble in ether, benzene and chloroform. It is neutral to litmus in an aqueous solution. For clinical purposes sulfanilamide has the desirable qualities of being easily administered and absorbed, when given by mouth, and is relatively inexpensive and of low toxicity.

MODE OF ACTION

When sulfanilamide is administered to mice immediately after experimental infection, it has a protective action so long as the chemical is given. It may protect the animal from several thousand minimal lethal doses of streptococci. If administration of the drug is delayed for several hours, however, or if the treatment is stopped before the animal recovers, it invariably dies. This demonstrates a bacteriostatic (growth-arresting) effect on the organism, although the exact site and mode of action are still unknown. Such an effect on streptococci *in vitro* has been shown in many experiments. A strongly bactericidal (organism-destructive) action has not been demonstrated *in vitro* or *in vivo*, except perhaps in the urine. Bliss and Long⁹ believe that sulfanilamide acts by inhibiting the growth of hemolytic streptococci, perhaps injuring the organisms in such a way as to permit them to be phagocytosed by the white blood cells. Leukocytes are essential in the action of this drug, but whether its effects are primarily on the bacteria or on the white blood cells has not been determined.

Various other hypotheses have been advanced to explain the mode of action of sulfanilamide. These include injury to the capsule of the organism, inhibition of toxin formation and specific activation of the reticuloendothelial system. The protective

action of the blood following sulfanilamide administration may be supplemented by that of the tissues of the whole animal, as suggested by Colebrook, Buttle and O'Meara.⁴ This notion of body immunity as a factor is further suggested by recent observations that, while first infections of gonorrhea do not respond to the treatment, after an individual has had the disease for a time, good therapeutic results may be obtained.

EFFECTS ON BODY TISSUES

Until the accidental deaths caused in October, 1937, by sulfanilamide in diethylene glycol solution (Elixir of Sulfanilamide—Massengill), little study has been made of the organs of animals purposely killed by this drug. Hawking¹⁰ gave toxic doses of sulfanilamide to rabbits and cats, and in those that recovered he found no histologic changes in the liver, kidneys or other viscera. Those animals which died from very large doses showed slight degenerative changes in the central nervous system in the form of chromatolysis in neurons of the anterior columns of the spinal cord, and in some of the nerve cells of the cortex and midbrain. In mice, Hageman¹¹ found some hemosiderin deposition in the spleen and slightly increased eosinophilia in the bone marrow.

Sulfanilamide could not be blamed as the cause of death in the patients who died after taking Elixir of Sulfanilamide. Necropsies and animal experiments showed that the cause was the diethylene glycol used as a vehicle. In the control studies on this problem done by Cannon,¹² two dogs and four rats were given sulfanilamide alone to see whether any tissue changes occurred. One dog and none of the rats experienced toxic manifestations. Autopsy revealed slight microscopic changes in the kidneys, consisting of moderate fatty degeneration in some of the collecting tubules of the dogs, but minimal in the rats. The livers of both dogs and rats showed no hydropic degeneration and practically no fatty changes. Sufficient observations on the organs of patients dying after sulfanilamide had been administered have not appeared. Although many of the clinical results reported following sulfanilamide treatment have been striking, its effect on body tissues in terms of late pathologic changes caused by this drug remains for the future to disclose.

CLINICAL USE

At present the clinical use of sulfanilamide is necessarily almost wholly empirical because the site and exact mode of action are not known. In the human subject, by any route of administration, the drug is readily absorbed and quickly diffused through the tissues. In this respect it is

The local application of the drug to the skin is useless

Puerperal Infection Reports of the results from sulfanilamide in the treatment of puerperal sepsis have been favorable. When the drug is given by mouth, it appears to prevent spread to the parametrial tissues, and septicemia is less apt to develop. Although difficult to evaluate, the mortality figures are given as reduced from about 25 per cent to from 5 to 8 per cent.¹⁹ With the usual methods of treatment for puerperal sepsis, organisms may be found present in stained smears from the cervix for as long as three or four weeks after recovery. The same is true after treatment with sulfanilamide, so that cervical smears are not necessarily a criterion

Scarlet Fever Results in the treatment of scarlatina have not been so striking. In the few reports available most cases have recovered, but the institution of sulfanilamide therapy during the acute stage of the illness did not appreciably accelerate the rate of recovery.²⁰ In a series of 150 cases reported by Peters and Havard,²¹ proseptasine—an English preparation, para-benzylaminobenzenesulfonamide—decreased the number of complications by about 20 per cent, but the patients treated had fever twelve hours longer than did the patients used as controls. The complications that may develop after scarlatina, such as otitis media, erysipelas and signs of renal damage, may respond favorably

Streptococcal Meningitis Sulfanilamide has proved its value clinically in this condition. Heretofore this disease was almost invariably fatal, with sulfanilamide treatment, reports^{17, 22, 23, 24, 25} of cases recovered are appearing with great rapidity. The oral use of the drug may be supplemented by intraspinal injection. In this combination Schwentker, Clason, Morgan, Lindsay and Long²⁷ advise the oral dose in smaller amounts than usually used, with treatment continued at the advised blood level for at least two days after the spinal fluid has been rendered sterile and a definite improvement has been seen. Because of the possibility of relapse, they also advise oral administration until the patient is entirely well.

MENINGOCOCCAL INFECTIONS

In infections of the meninges by the meningococcus, sulfanilamide has been responsible for the saving of lives. While the results are not so startling in some cases as in cases of streptococcal meningitis, as the data of larger series are reported a definite decrease in the mortality rate is being shown. Sulfanilamide is effective against Types I and II of the meningococcus, which may be an advantage over serum therapy. In the latter,

a polyvalent serum may not contain the specific antibodies against the particular strain infecting a given patient. In a further comparison, Brown²⁸ has demonstrated that the protective influence of 8 mg of para-aminobenzenesulfonamide is comparable to 0.1 cc. of highly potent antimeningococcal serum. Serum may be used alternately with sulfanilamide given intraspinally.

In the meningococcemia associated with meningitis, sulfanilamide by mouth is effective in rapidly clearing the blood stream of organisms. Very few reports of meningococcemia without meningitis treated with sulfanilamide have been made to date.

GNORRHOEAL INFECTIONS

As was to be expected because of the close biologic relation of the gonococcus to the meningococcus, sulfanilamide was applied to the treatment of gonorrhea after beneficial results had been obtained in meningococcal infections. The first reports were extremely favorable, but as data accumulate more and more failures occur. Ninety per cent cures have been reported by Reuter,²⁹ and the Mayo Clinic³⁰ gives 90 per cent for male and 80 per cent for female patients. Instead of simply dividing the cases into acute and chronic, Herold²⁹ paid particular attention to first infections and found that the patients respond poorly if at all. All so-called cures in his series were in patients who had had gonorrhea for some time. In a more recent report³⁰ of 72 cases treated and adequately followed, there were 12 complete failures and only 14 cures.

Sulfanilamide may cause the organisms to disappear from the stained smears in from two to six days. However, this may give a false sense of security to both patient and physician as to adequate treatment and cure. It is apparently effective in some cases in preventing an extension of the infection to the posterior urethra and prostate.

In the chronic cases, in which the drug seems to be the most effective, Dees and Colston³¹ originally outlined the oral dose as follows: 4.8 gm daily for two days, 3.6 gm for three days, and 2.4 gm for from four to eight days. More recently Walther³² has considered this dosage too large, and has advised beginning with smaller doses and gradually increasing the amount for example, 1.2 gm for two days, 2.4 gm for two days and an increase to 4.8 gm daily as tolerated. It is unwise to attempt the treatment of gonorrhea by the injection of sulfanilamide into the urethra.

The results in the treatment of gonococcal arthritis have been too few to warrant definite conclusions. Keefer³³ has found it possible to sterilize the synovial fluid within two days after the oral

body weight may be necessary, and seems to be well tolerated. Several tablets are to be given at intervals of from four to six hours. In critical illness, such as streptococcal septicemia or meningitis, from 4 to 5 gm. may be given in the first four or six hours in order to obtain the desired blood level. The dose may then be reduced daily as the fever subsides and the patient improves. Owing to the tendency of streptococcal infections to recur, the drug usually must be given until the patient is well on the way to recovery.

A second method of administration used where the patient is not critically ill, as in urinary infections, is to begin with smaller doses, as 2.0 gm (30 gr) the first day, 2.5 gm the second, and so forth, increasing the dose until the desired blood level has been obtained.

In patients with nausea, vomiting or coma, in whom administration by mouth is impractical, parenteral routes may be used.

Parenteral Administration For parenteral administration, two substances are available, the red prontosil (disodium salt) solution for intramuscular use, and the white crystalline sulfanilamide powder, within its limits of solubility, for subcutaneous or intrathecal injection. The tablet for oral use cannot be dissolved for parenteral administration.

Although used rather extensively when the drug was first placed on the market, the red prontosil solution for intramuscular injection has become less popular than formerly. When given, it is used in patients weighing less than 150 lb on the basis of 1 cc. per pound of body weight as the total daily dose, to be given at six-hour intervals. In individuals weighing more, the dose is 0.75 cc per pound of body weight. Prontosil in this form colors the skin and the urine from pink to red. It has been found inadvisable in intraspinal therapy.¹⁷ Prontosil is thought to be decomposed in the body with the formation of para-aminobenzenesulfonamide.

The sulfanilamide powder is soluble up to 0.8 per cent in physiologic saline, and is used in this form for subcutaneous and intrathecal injections. It is best to prepare the solution each day, even though it is fairly stable when kept at room temperature, because if it is placed on ice, the sulfanilamide rapidly crystallizes out of solution. To prepare such a solution, bring 100 cc. of sterile physiologic saline to a boil, add 0.8 gm. of the white crystalline powder and dissolve by the aid of shaking, inject when the solution has cooled to 37°C. The dose for hypodermoclysis is as follows: for individuals weighing up to 40 lb, 100 cc., from 40 to 80 lb, 200 cc., from 80 to 120 lb, 300 cc., and over 120 lb, 400 cc. A satisfactory initial dose for

adults is from 400 to 700 cc. The dose for intraspinal injection is from 15 to 30 cc. at from six- to eight-hour intervals. Slightly more cerebrospinal fluid than the quantity of sulfanilamide solution to be injected having been removed, the latter should be administered by gravity method, never under pressure. This solution has also been advocated for rectal administration, the amount of the dose, however, cannot be accurately given, as the rate of absorption of sulfanilamide from the colon and rectum is unknown.

The red prontosil or the sulfanilamide saline solution should never be given intravenously, since the excretion of the drug by the kidneys is so rapid that an adequate level of concentration in the blood is difficult to maintain. This method of administration is unnecessary, as the oral or subcutaneous routes are very effective in clearing the blood stream of susceptible organisms. Furthermore, untoward reactions are common when the drug is given by vein.

STREPTOCOCCAL INFECTIONS

Sulfanilamide and its related compounds were originally introduced for the treatment of infections due to beta-hemolytic streptococci, and are effective against most strains of this organism, but not all.¹⁴ Results from this drug in the treatment of bacteremia and septicemia are favorable in that the blood stream may be cleared quite rapidly of the streptococci. However, isolated foci of streptococcal infection that may exist with the septicemia may not be affected.

Without a critical classification of the invading organisms, sulfanilamide and related substances have been used in the treatment of erysipelas, puerperal sepsis, tonsillitis, peritonitis, scarlet fever, meningitis, otitis media, Ludwig's angina and osteomyelitis. In throat infections, peritonitis and osteomyelitis (except isolated instances of mastoiditis), the effects of treatment with this drug alone have not been remarkable. The other conditions will be considered separately.

Erysipelas In erysipelas and streptococcal cellulitis, good therapeutic results have been obtained. Of the many studies reported in the literature, one of the largest and best controlled is that of Snodgrass and Anderson.¹⁸ These authors treated a total of 312 cases, and found that the prontosil they used promptly reduced the fever, prevented spread of the infection and decreased the duration of the toxemia. Old and young alike with this condition tolerated the drug well. Sulfanilamide seemed effective in decreasing the complications that follow erysipelas, but it did not necessarily prevent recurrences. When it is given orally, other therapeutic measures such as ointments are unnecessary.

The local application of the drug to the skin is useless.

Puerperal Infection Reports of the results from sulfanilamide in the treatment of puerperal sepsis have been favorable. When the drug is given by mouth, it appears to prevent spread to the parametrial tissues, and septicemia is less apt to develop. Although difficult to evaluate, the mortality figures are given as reduced from about 25 per cent to from 5 to 8 per cent¹⁹. With the usual methods of treatment for puerperal sepsis, organisms may be found present in stained smears from the cervix for as long as three or four weeks after recovery. The same is true after treatment with sulfanilamide, so that cervical smears are not necessarily a criterion.

Scarlet Fever Results in the treatment of scarlatina have not been so striking. In the few reports available most cases have recovered, but the institution of sulfanilamide therapy during the acute stage of the illness did not appreciably accelerate the rate of recovery²⁰. In a series of 150 cases reported by Peters and Havard,²¹ proseptasine—an English preparation, para-benzylaminobenzene-sulfonamide—decreased the number of complications by about 20 per cent, but the patients treated had fever twelve hours longer than did the patients used as controls. The complications that may develop after scarlatina, such as otitis media, erysipelas and signs of renal damage, may respond favorably.

Streptococcal Meningitis Sulfanilamide has proved its value clinically in this condition. Heretofore this disease was almost invariably fatal, with sulfanilamide treatment, reports^{17, 22, 23, 24, 25} of cases recovered are appearing with great rapidity. The oral use of the drug may be supplemented by intraspinal injection. In this combination Schwentker, Clason, Morgan, Lindsay and Long²⁶ advise the oral dose in smaller amounts than usually used, with treatment continued at the advised blood level for at least two days after the spinal fluid has been rendered sterile and a definite improvement has been seen. Because of the possibility of relapse, they also advise oral administration until the patient is entirely well.

MENTINGOCOCCAL INFECTIONS

In infections of the meninges by the meningococcus, sulfanilamide has been responsible for the saving of lives. While the results are not so startling in some cases as in cases of streptococcal meningitis, as the data of larger series are reported a definite decrease in the mortality rate is being shown. Sulfanilamide is effective against Types I and II of the meningococcus, which may be an advantage over serum therapy. In the latter,

a polyvalent serum may not contain the specific antibodies against the particular strain infecting a given patient. In a further comparison, Brown²⁸ has demonstrated that the protective influence of 8 mg of para-aminobenzenesulfonamide is comparable to 0.1 cc. of highly potent antimeningococcal serum. Serum may be used alternately with sulfanilamide given intraspinaly.

In the meningococcemia associated with meningitis, sulfanilamide by mouth is effective in rapidly clearing the blood stream of organisms. Very few reports of meningococcemia without meningitis treated with sulfanilamide have been made to date.

GNOCOCOCCAL INFECTIONS

As was to be expected because of the close biologic relation of the gonococcus to the meningococcus, sulfanilamide was applied to the treatment of gonorrhea after beneficial results had been obtained in meningococcal infections. The first reports were extremely favorable, but as data accumulate more and more failures occur. Ninety per cent cures have been reported by Reuter,²⁷ and the Mayo Clinic²⁸ gives 90 per cent for male and 80 per cent for female patients. Instead of simply dividing the cases into acute and chronic, Herrold²⁹ paid particular attention to first infections and found that the patients respond poorly if at all. All so-called cures in his series were in patients who had had gonorrhea for some time. In a more recent report³⁰ of 72 cases treated and adequately followed, there were 12 complete failures and only 14 cures.

Sulfanilamide may cause the organisms to disappear from the stained smears in from two to six days. However, this may give a false sense of security to both patient and physician as to adequate treatment and cure. It is apparently effective in some cases in preventing an extension of the infection to the posterior urethra and prostate.

In the chronic cases, in which the drug seems to be the most effective, Dees and Colston³¹ originally outlined the oral dose as follows: 4.8 gm daily for two days, 3.6 gm for three days, and 2.4 gm for from four to eight days. More recently Walther³² has considered this dosage too large, and has advised beginning with smaller doses and gradually increasing the amount for example, 1.2 gm for two days, 2.4 gm for two days and an increase to 4.8 gm daily as tolerated. It is unwise to attempt the treatment of gonorrhea by the injection of sulfanilamide into the urethra.

The results in the treatment of gonococcal arthritis have been too few to warrant definite conclusions. Keefer³³ has found it possible to sterilize the synovial fluid within two days after the oral

body weight may be necessary, and seems to be well tolerated. Several tablets are to be given at intervals of from four to six hours. In critical illness, such as streptococcal septicemia or meningitis, from 4 to 5 gm may be given in the first four or six hours in order to obtain the desired blood level. The dose may then be reduced daily as the fever subsides and the patient improves. Owing to the tendency of streptococcal infections to recur, the drug usually must be given until the patient is well on the way to recovery.

A second method of administration used where the patient is not critically ill, as in urinary infections, is to begin with smaller doses, as 2.0 gm (30 gr) the first day, 2.5 gm the second, and so forth, increasing the dose until the desired blood level has been obtained.

In patients with nausea, vomiting or coma, in whom administration by mouth is impractical, parenteral routes may be used.

Parenteral Administration For parenteral administration, two substances are available, the red prontosil (disodium salt) solution for intramuscular use, and the white crystalline sulfanilamide powder, within its limits of solubility, for subcutaneous or intrathecal injection. The tablet for oral use cannot be dissolved for parenteral administration.

Although used rather extensively when the drug was first placed on the market, the red prontosil solution for intramuscular injection has become less popular than formerly. When given, it is used in patients weighing less than 150 lb on the basis of 1 cc per pound of body weight as the total daily dose, to be given at six-hour intervals. In individuals weighing more, the dose is 0.75 cc per pound of body weight. Prontosil in this form colors the skin and the urine from pink to red. It has been found inadvisable in intraspinal therapy.¹⁷ Prontosil is thought to be decomposed in the body with the formation of para-aminobenzenesulfonamide.

The sulfanilamide powder is soluble up to 0.8 per cent in physiologic saline, and is used in this form for subcutaneous and intrathecal injections. It is best to prepare the solution each day, even though it is fairly stable when kept at room temperature, because if it is placed on ice, the sulfanilamide rapidly crystallizes out of solution. To prepare such a solution, bring 100 cc of sterile physiologic saline to a boil, add 0.8 gm of the white crystalline powder and dissolve by the aid of shaking, inject when the solution has cooled to 37°C. The dose for hypodermoclysis is as follows: for individuals weighing up to 40 lb, 100 cc; from 40 to 80 lb, 200 cc; from 80 to 120 lb, 300 cc; and over 120 lb, 400 cc. A satisfactory initial dose for

adults is from 400 to 700 cc. The dose for intraspinal injection is from 15 to 30 cc at from six to eight-hour intervals. Slightly more cerebrospinal fluid than the quantity of sulfanilamide solution to be injected having been removed, the latter should be administered by gravity method, never under pressure. This solution has also been advocated for rectal administration, the amount of the dose, however, cannot be accurately given, as the rate of absorption of sulfanilamide from the colon and rectum is unknown.

The red prontosil or the sulfanilamide saline solution should never be given intravenously, since the excretion of the drug by the kidneys is so rapid that an adequate level of concentration in the blood is difficult to maintain. This method of administration is unnecessary, as the oral or subcutaneous routes are very effective in clearing the blood stream of susceptible organisms. Furthermore, untoward reactions are common when the drug is given by vein.

STREPTOCOCCAL INFECTIONS

Sulfanilamide and its related compounds were originally introduced for the treatment of infections due to beta-hemolytic streptococci, and are effective against most strains of this organism, but not all.¹⁴ Results from this drug in the treatment of bacteremia and septicemia are favorable in that the blood stream may be cleared quite rapidly of the streptococci. However, isolated foci of streptococcal infection that may exist with the septicemia may not be affected.

Without a critical classification of the invading organisms, sulfanilamide and related substances have been used in the treatment of erysipelas, puerperal sepsis, tonsillitis, peritonitis, scarlet fever, meningitis, otitis media, Ludwig's angina and osteomyelitis. In throat infections, peritonitis and osteomyelitis (except isolated instances of mastoiditis), the effects of treatment with this drug alone have not been remarkable. The other conditions will be considered separately.

Erysipelas In erysipelas and streptococcal cellulitis, good therapeutic results have been obtained. Of the many studies reported in the literature, one of the largest and best controlled is that of Snodgrass and Anderson.¹⁸ These authors treated a total of 312 cases, and found that the prontosil they used promptly reduced the fever, prevented spread of the infection and decreased the duration of the toxemia. Old and young alike with this condition tolerated the drug well. Sulfanilamide seemed effective in decreasing the complications that follow erysipelas, but it did not necessarily prevent recurrences. When it is given orally, other therapeutic measures such as ointments are unnecessary.

that it is the drug of choice in the average case, and that it is usually easier to get a urine slightly alkaline for sulfanilamide action than to obtain a pH of 5.5 necessary for mandelic acid. Thus, with one drug acting only in an acid medium and the other giving the best results in an alkaline medium, the two supplement each other, and should be used in the treatment of urinary infections according to the organisms causing them.

OTHER ORGANISMS AND INFECTIONS

The widespread enthusiasm over sulfanilamide and its therapeutic possibilities has caused it to be tried in almost every type of infection, even far removed from those due to the streptococcus. Many of the studies have been confined to the test tube, where the effect of this drug has been tried on *Bacillus typhosus*, *B. paratyphosus A* and *B*, *B. dysenteriae* (Flexner, Shiga) and related gram-negative bacilli,⁴⁵ and *Hemophilus influenzae*⁴⁶ without any action.

In animal experiments with mice, Buttle and his associates⁴⁷ found sulfanilamide to give some protection against *B. typhosus*, *B. paratyphosus B*, *B. aertrycke*, Friedländer's bacillus, *Pasteurella pseudotuberculosis* and *P. septicus*. In the same animal it is ineffective against the viruses of encephalitis (St. Louis type) and of benign lymphocytic choriomeningitis.⁴⁸ Protosil was effective in rabbits in infections caused by the latter but ineffective in herpes-virus infection and also in that due to the virus of lymphogranuloma inguinale in monkeys.⁴⁹ In the rabbit, sulfanilamide had no effect on *Treponema pallidum*.⁴⁹

In human patients, sulfanilamide has been found to be relatively ineffective in staphylococcal infections (except in the urine), *Streptococcus viridans* endocarditis, rheumatic fever and chorea. Massell⁵⁰ found a failure of the drug to prevent the recurrence of rheumatic fever after streptococcal sore throat treated with sulfanilamide. In the treatment of gas gangrene due to *B. welchii* the drug has met with some degree of success.⁵¹ In a few cases it has been reported as effective in the treatment of malaria, both acquired⁵² and induced.⁵³

In mixed infections, such as those due to streptococci and staphylococci, the drug may be of benefit. Equivocal results have been reported in the treatment of streptococcal infections complicating tuberculosis.⁵⁴ Isolated instances have occurred in which the condition of patients with tuberculosis has been made definitely worse by sulfanilamide.

TOXIC EFFECTS

Untoward reactions, even death, may result from the administration of sulfanilamide, a fact which

in several communities has prompted legislation regarding the sale and use of this drug.⁵⁵ The toxic effects are more commonly the result of its indiscriminate use, but may occur from an idiosyncrasy to it. They may be classed as of three types: mild, moderate and severe. The mild symptoms consist of headache, anorexia, vertigo and general malaise, with possible slight cyanosis and dyspnea. The moderate reactions may be classed as a progression of any of the foregoing symptoms, with special reference to cyanosis and dyspnea. The severe reactions may result in persistent sulfhemoglobinemia, skin manifestations, hyperpyrexia or hypopyrexia, abdominal and chest pains, tachycardia, persistent dyspnea, diarrhea and numbness and tingling of the hands and feet. Marked disturbances of the blood, such as anemia, jaundice, leukopenia and agranulocytosis, may occur. The severe manifestations may result in collapse and death.

A lowering of the blood-plasma carbon-dioxide-combining power commonly occurs following the administration of sulfanilamide.⁵⁶

Buchtel and Cook⁴² have found that 15 per cent of patients cannot take large doses of sulfanilamide, and 10 per cent are unable to tolerate it at all. Patients in bed tolerate larger doses than do those who are ambulatory. Several investigators have pointed out that ambulatory patients exposed to sunlight are more apt than are others to develop a skin rash after sulfanilamide. In general, children tolerate the drug better than do adults. Elderly patients with cardiac, renal or hepatic involvement cannot stand the larger doses as can others.

The commonest symptoms of sulfanilamide toxicity are cyanosis and dyspnea. Cyanosis occurs in about 75 per cent of patients receiving the drug, and may appear early. It is thought to be due to methemoglobin or sulfhemoglobin formation, or to a peculiar red-cell-binding pigment in the blood.⁵⁷ In the former case it is usually transient in character and does not have lasting effects. It can be determined spectroscopically, yielding a band at a wave length of 562 m μ . Sulfhemoglobinemia, on the other hand, as demonstrated by Colebrook and Kenny,¹⁹ Discombe,⁵⁸ and Paton and Eaton,⁵⁹ is of a more lasting character and may be responsible for many symptoms and pathologic changes. It yields a band in the absorption spectrum at 620 m μ . Naturally, sulfhemoglobinemia can reduce the oxygen capacity of the blood, but it need not affect the hemoglobin content as determined by routine colorimetric methods.

According to the more recent studies of Archer and Discombe,⁶⁰ any preparations which are liable to produce a watery stool in the patient, such as magnesium sulfate and other cathartics, may ag-

administration of sulfanilamide. He considers this evidence that sulfanilamide may be effective in the treatment of gonococcal arthritis, particularly in patients with an infected synovial fluid. Keefer's studies³⁴ have shown further that after several days' treatment the blood becomes bactericidal as well as bacteriostatic. That the drug does not hinder natural immunologic processes is suggested by the failure of sulfanilamide to influence the gonococcal complement-fixation reaction of the blood.

PNEUMOCOCCAL INFECTIONS

Domagk's original report stated that prontosil was ineffective against pneumococci, and Horel's³⁵ later communication revealed equivocal results. In experimental pneumococcal infections in animals, rats, mice and rabbits have varied in their responses to sulfanilamide, with conflicting conclusions resulting. Pneumococcal pneumonia in the rat approximates most closely that seen in the human subject, and in experiments with this test animal the drug has been effective in combating Types I, II, III and XIV. In patients, however, the results have not been striking. Most conservative clinicians have been satisfied to treat Types I and II with serum. As a result, no adequate series of cases treated with sulfanilamide has appeared. With serum not yet available, Heintzelman, Hadley and Mellon³⁶ have shown good results in the treatment of the highly fatal Type III with sulfanilamide. In their series of 19 cases, of which 9 were treated and 10 were controls, 7 treated patients recovered, a mortality of 22 per cent. With 23 cases in their community added to the untreated cases, 9 patients recovered, a mortality of 73 per cent. Many more data are essential, however, before sulfanilamide can be accepted as an effective therapeutic agent in the treatment of pneumococcal pneumonia.

In other infections due to pneumococcus, such as otitis media and mastoiditis, sulfanilamide may be of benefit.³⁷ A temporary improvement in patients with pneumococcal meningitis with a reduction in the organisms and cells in the cerebrospinal fluid has been noted, but no recoveries following sulfanilamide therapy have been reported.

URINARY TRACT INFECTIONS

Sulfanilamide has proved of distinct value in the treatment of certain infections of the urinary tract. Marshall, Emerson and Cutting³⁸ compared the renal clearance of sulfanilamide with a simultaneously obtained creatinine clearance, and found the former from 20 to 30 per cent of the latter. Their studies indicate that the drug is excreted entirely by glomerular filtration and that from 70

to 80 per cent of it is reabsorbed by the tubules. The concentration in which it is excreted depends upon the amount administered and upon the function of the kidneys.

Helmholz and his co-workers^{39 40 41 42 43} at the Mayo Clinic have made extensive studies with sulfanilamide in the treatment of urinary sepsis. In the human subject, sulfanilamide is excreted in the urine chiefly in two forms, in the free state and as para-acetylamino benzenesulfonamide. The experiments of Helmholz and Osterberg⁴³ indicate that concentrations of free sulfanilamide of from 30 to 40 mg per 100 cc of urine are necessary in order to obtain good bactericidal action, but occasionally even at lower concentrations there is a bacteriostatic effect. From 3 to 4 gm of sulfanilamide a day gives a urinary excretion of from 60 to 125 mg of free sulfanilamide and from 50 to 100 mg conjugated as the para-acetyl salt. In the case of impaired kidney function the drug is excreted in the urine in lower concentrations, so that it is retained in the blood stream to give a higher blood level, which may result in toxic manifestations. However, when used cautiously (Helmholz and Osterberg) a lower urinary concentration of the drug has been found effective in treating infection of the urinary tract in spite of an elevated blood urea nitrogen.

Sulfanilamide given by mouth has been found effective in the treatment of urinary sepsis due to *Staphylococcus aureus*, *Bacillus coli* and *Aerobacter aerogenes*, and in some cases due to *Proteus vulgaris* and to *Pseudomonas seruginosa*. In infections due to *Streptococcus fecalis* the drug is ineffective. In general, bacillary infections respond more favorably than do those due to cocci.

Sulfanilamide is usually more effective in an alkaline than in an acid urine. Consequently, it may be advisable to administer from 0.3 to 0.6 gm (5 to 10 gr) of sodium bicarbonate with each dose. In order to act in an acid urine the concentration of sulfanilamide must be higher than in the case of an alkaline urine.

An effective dose by mouth, as outlined by Helmholz, consists, in adults, in 2.0 gm the first day, 2.6 gm the second day, 4.0 gm the third day and so on, with a gradual decrease as the desired blood and urinary concentrations are obtained and good clinical results are observed. In general, patients taking larger doses show a more satisfactory response. The daily dose for infants is from 0.3 to 0.6 gm, and for children of twelve, 2.0 gm.

In comparing sulfanilamide with the recently introduced mandelic acid in the treatment of urinary tract infections, Helmholz⁴⁴ points out that each has its place. The advantages of sulfanilamide are that it can be used in acute infections,

long-continued administration have yet to be disclosed

gravate the deleterious effects of sulfanilamide in causing sulfhemoglobinemia. Hydrochloric acid and coal-tar derivatives may act similarly. Sulfhemoglobinemia, however, may develop from sulfanilamide therapy alone. Patients may develop both methemoglobinemia and sulfhemoglobinemia, but not usually at the same time.

The blood should be examined frequently for the possible development of anemia. A lowering of the hemoglobin and red-cell content of the peripheral blood occurs rather commonly after sulfanilamide administration. Severe anemias, as reported by Harvey and Janeway,⁶¹ may result, and may be hemolytic or aplastic in character. These authors compared the anemia which they observed with the hemolytic crises produced by phenylhydrazine. It is of interest that in the cases of anemia reported by them, and similarly in those reported by Kohn,⁶² as the anemia developed the white-cell count rose, with many immature forms present. In the necropsy study by Borst,⁶³ in which the patient died with agranulocytosis, study of the bone marrow was inconclusive.

That drugs possessing in common a benzene ring with an attached NH_2 or amine group, which increases the ease of oxidation, may cause agranulocytosis in susceptible individuals was suggested by Kracke.⁶⁴ This may be significant in regard to sulfanilamide, since it is such a benzene-ring compound, and since instances of agranulocytosis following its use have occurred. Serial leukocyte counts in patients receiving the drug may show either an increase or a decrease in white blood cells. In Borst's case of agranulocytosis the patient had had a previous blood disorder, which may have been a factor. Frequent white-blood-cell counts in the case reported by Young⁶⁵ gave no warning of the impending disaster.

When hyperpyrexia occurs as a toxic manifestation of sulfanilamide therapy, it may be difficult to tell whether it is due to the drug or to the infection for which it is being given. As described by Hageman and Blake,⁶⁶ it is usually abrupt in onset and may occur at any time. In their series it occurred in 21 of 134 cases, an incidence of 16 per cent. The reaction varies in intensity and the average duration is from two to four days, with prolongation in cases in which the drug is continued. Eosinophilia of from 1 to 6 per cent was present in about half their 21 cases. The condition may very closely simulate serum sickness, skin tests for sensitivity showed no positive reactions.

Skin rashes occurring after sulfanilamide are of various forms, simulating measles, scarlet fever, urticaria and erythema multiforme. They may resemble the reactions from the barbiturates.⁶⁷ The

eruption occurs most commonly on the face, trunk and extremities, and may or may not be accompanied by fever. In certain ambulatory cases reported there seems to have been a definite relation between the development of a rash and exposure to sunlight. Positive skin tests have occasionally been reported.

Although tissue reactions to any appreciable degree have not occurred in animal experiments with sulfanilamide, nephropathies in human subjects have been reported. Colebrook and Kenny¹⁹ state that 40 per cent of 38 patients studied showed red blood cells and casts in the urine, while 20 per cent had an increase in urinary albumin content over that originally present. Definite nephritis has been reported.⁶⁸ It may be difficult, however, to evaluate the relation of the nephropathy to the drug or to the infection, since Anghelscu et al.⁶⁹ and others have successfully treated cases of erysipelas with concurrent renal disease.

Treatment of Toxic Manifestations The treatment of toxic manifestations from sulfanilamide administration depends to some extent on the nature of the reaction. Methemoglobinemia is a common finding, and the cyanosis alone does not contraindicate the use of the drug, but it must be continued cautiously. With all other types of reaction administration of the drug should be stopped. Because sulfanilamide is so rapidly and practically completely excreted in the urine, fluids should be forced. Archer and Discombe⁶⁰ have outlined certain principles for the prevention of sulfhemoglobinemia. They advise the use of no other drugs with sulfanilamide, except for sodium bicarbonate, employed in order to obtain an alkaline urine or to combat acidosis. The colon should be kept free from food residues by a cleansing enema before treatment is started, and a low-residue diet of adequate caloric value but containing few eggs should be given. When sulfhemoglobinemia occurs, the only treatment is blood transfusion. This is also the treatment for severe anemia, as liver and iron are apparently not effective. The administration of oxygen may be helpful in cases of methemoglobinemia.

SUMMARY

Sulfanilamide appears to have proved its worth as an effective chemotherapeutic agent in the treatment of certain infections. From the more important facts here summarized it can be clearly seen that it is not a panacea. Since there is no shorter road to the discredit of any drug than its indiscriminate use, emphasis has been placed upon methods of administration, dosages and toxic effects. Clearer indications and contraindications to its use and the possible deleterious effects of its

volving the intima and the media. Nearby there was another slit in the aorta about 1 cm. in length. From the base of the aorta the wall was dissected down to the mouth of the celiac artery, where the dissection through the intima reruptured into the aorta. Below this point the aorta was intact. There was a small extravasation of blood into the posterior mediastinum. Scattered over the intima of the entire aorta there were small, raised, yellowish, atheromatous deposits.

Histologic examination of the myocardium revealed changes indicating acute infarction. The inner half of the myocardium of the left ventricle contained massive infiltration of the stroma by polymorphonuclear leukocytes. There was also occasional invasion of the muscle fibers, which showed hyalinization with karyolysis. Sections of the aorta revealed an essentially normal structure.

sinus rhythm with a rate of 79 per minute. The P R interval was 0.16 second. T₁ was upright, T₂ low, T₃ inverted. There was left ventricular preponderance. The diagnosis was essential hypertension, and there was serologic evidence of syphilis.

The patient was admitted to the hospital on August 9, 1937, in a state of circulatory collapse. She was unable to give an adequate history. On the day of admission she suddenly experienced a severe, sharp pain in the middle of the back of her thorax. Subsequently the pain was felt in the substernal and subxiphoid regions. Because of the severity of the pain she was barely able to breathe. On physical examination she was found to be anxious and pale, and covered with cold, beaded perspiration. The heart rate was rapid and regular. The sounds were barely audible. The blood pressure was 60/40. The temperature

Figure 1 *Electrocardiograms in Case 1 before (12/8/36) and after (11/4/37 and 11/5/37) the onset of dissecting aneurysm, reproduced in respective order*

The anatomic diagnoses were as follows: dissecting aneurysm of the aorta with hemopericardium, pulmonary congestion and edema, compression of the mouth of the left coronary artery caused by dissection of this artery, myocardial infarction of the left ventricle, healed chronic pyelonephritis, moderate atherosclerosis of the aorta, and healed cholecystitis.

Case 2 A 61-year-old, white woman was observed in the Outpatient Department on several occasions between July 9 and July 22, 1937. Her main complaints were insomnia and dizziness of 3 years duration. She had known since 1925 that she had "high blood pressure." Her mother died of "high blood pressure" at the age of 55. One brother died from "lifting" at the age of 32. Her husband died insane.

Physical examination indicated a moderately enlarged heart with regular rhythm. There was an apical systolic murmur. The blood pressure on two occasions was 204/120 and 200/110. The rest of the examination was unessential. Blood Wassermann and Hinton tests were positive. An electrocardiogram on July 16, 1937, showed

was 99°F. The blood count showed 3,000,000 red cells, with a hemoglobin of 60% and 14,800 white cells. A blood Hinton test was positive. The electrocardiogram revealed normal sinus rhythm. T₁ and T₂ were upright, T₃ diphasic. The chest lead (chest electrode, fifth interspace 8 cm from midline, and left leg) was diphasic (abnormal), there was left ventricular preponderance (Fig 2). There were only minor changes since the electrocardiogram taken on July 16.

The day after admission the patient's condition was somewhat improved. The heart was found to be displaced to the right. Signs of fluid appeared in the left chest, and a tap yielded 50 cc. of bloody fluid. The patient failed to respond to oxygen and shock therapy and died on August 11. A diagnosis of luecic and arteriosclerotic heart disease with dissecting aneurysm was made.

The following were the pertinent findings at post-mortem examination. The left pleural cavity contained about 1500 cc. of clotted blood. The left half of the posterior mediastinum was swollen because of the pres-

DISSECTING ANEURYSM OF THE AORTA

Two Cases with Unusual Features

SOMA WEISS, MD*

BOSTON

RECENT definition of the clinical course of dissecting aneurysm of the aorta has resulted in its more frequent recognition. Whereas up to 1935 the condition was diagnosed in but some half-dozen instances, an appreciable number of cases have been correctly diagnosed during the past three years.^{1 2 3} Recognition of a case with a typical clinical course is no longer difficult. Indeed, the clinical picture may be specific. Cases with a "silent" or atypical course, on the other hand, usually escape recognition.

In the differential diagnosis, coronary thrombosis offers the main difficulty. The presence of syphilitic aortitis or aneurysm is considered by most writers² as evidence against the presence of dissecting aneurysm. The inflammatory reactions caused by syphilis tend to fuse the layers of the aorta, thereby making dissection difficult if not impossible. Syphilitic aneurysm usually becomes thinned out and ruptures without dissection.

The following 2 cases are reported because they demonstrate that dissecting aneurysm can cause coronary occlusion and myocardial infarction, and that syphilitic and dissecting aneurysm may co-exist.

CASE REPORTS

Case 1 A 40-year-old, male Filipino was first observed in December, 1936. For 7 years he had experienced mild epigastric distress. For 6 months he had noted subcardiac and more severe epigastric distress, and had dyspnea and palpitation on exertion. The discomfort appeared after eating, was nonradiating and was relieved by soda. The day before entering the hospital he vomited coffee ground material and on four occasions had tarry stools.

Physical examination revealed slight sclerosis of the vessels of the eyegrounds. The heart was slightly enlarged. The rhythm was regular. There was a soft systolic murmur. The aortic second sound was ringing. The arterial pressure varied from 168/106 to 178/120. The rest of the findings were unessential. The urine revealed no abnormalities. There was a severe degree of secondary anemia, with a red-blood-cell count of 2,400,000 and a hemoglobin of 34%. The white-blood-cell count was 13,800. The stools were tarry and the guaiac test was 4+. A blood Hinton test was negative. X ray study of the gastrointestinal canal revealed changes diagnosed as gastric and duodenal ulcers. The electrocardiogram revealed changes consistent with digitalis effect. The rest of the tests were unessential.

From Thorodike Memorial Laboratory. Second and Fourth Medical Services (Harvard) Boston City Hospital and the Department of Medicine Harvard Medical School.

Read before a meeting of the New England Heart Association Boston December 13 1937.

*Associate professor of medicine, Harvard Medical School director Second and Fourth Medical Services (Harvard) and associate physician Thorodike Memorial Laboratory Boston City Hospital.

Following the use of Sippy diet and administration of iron, the gastric symptoms and the anemia decreased. The diagnoses were peptic ulcers, essential hypertension and a slight degree of arteriosclerosis.

After leaving the hospital the patient continued to feel well. He lost his position, however, because "high blood pressure" was discovered on routine physical examination. At 1:30 a.m. on November 2, 1937, he experienced sudden breathlessness and orthopnea, which continued for several hours. In the afternoon of the same day he developed sharp, burning, boring, nonradiating pain in the epigastrium. When he entered the hospital 2 days later he was weak and irritable. The radial pulse was imperceptible and the arterial pressure could not be measured. In a few hours he improved somewhat.

Physical examination revealed an anxious patient with slight cyanosis. The heart was moderately enlarged. The pulse rate was from 130 to 140 and regular. The sounds were weak. The pulmonary second sound was accentuated and the aortic second sound was barely audible. The blood pressure was 100/55. The lungs were normal. There was tenderness in the epigastrium, but no spasm. The other findings were irrelevant. The red-blood-cell count was 6,000,000 and the hemoglobin 95%. The white blood cells on two occasions numbered 27,600 and 21,300. The nonprotein nitrogen of the blood was 46 mg per cent. The x ray picture of the chest showed widening of the aorta. The electrocardiogram taken on November 4 showed T₁ and T₂ diphasic, T₃ upright, T₄ (chest electrode, fifth interspace 6 cm. from midline, and left leg) inverted (normal), and left ventricular preponderance. There was sinusauricular tachycardia, with a pulse rate of 107. The electrocardiogram was interpreted as indicating myocardial disease. The next day, however, T₁, T₂ and T₃ were diphasic and T₄ was inverted. There was a prolonged Q-T interval, K equaled 0.47 (Fig 1). Because of changes in the T waves within 24 hours, an acute myocardial process, possibly coronary thrombosis, was considered likely, although the electrocardiographic changes were not characteristic of thrombosis. The rest of the laboratory findings were unessential. The general condition remained practically unaltered when, 2 days after admission, the patient suddenly collapsed, developed convulsions and died.

The differential diagnosis rested between coronary thrombosis and perforated gastric ulcer.

The essential findings at postmortem were as follows. The pericardial sac was distended and contained about 200 cc. of clotted blood. At the root of the pulmonary artery and the aorta there were extensive hemorrhagic extravasations into the adventitial tissue. The heart weighed 500 gm. The myocardium of the lateral aspect of the left ventricle was lighter than the normal portions and contained yellowish and reddish areas. About the mouths of both coronary arteries there was a marked degree of extravasation of blood. The left coronary artery was compressed near its opening by a dissection which extended to a distance of about 1 cm. from the orifice. The coronary arteries contained no thrombus.

About 1 cm. above the aortic valve there was a sharp, cleftlike rupture approximately 4 cm. in length, in

Figure 3 Appearance of the aorta and of the opening of the old syphilitic aneurysm: acute tear of the intima leading to the dissection toward the base of the heart and to the abdominal aorta (upper picture) Transverse section at the level of the third thoracic vertebra showing the relation of the acute dissection to the syphilitic aneurysm: note erosion of part of the vertebral body by the syphilitic aneurysm (lower picture)

ence of considerable dark blood. At the level of the ninth thoracic vertebra there was roughening of the parietal pleura, which appeared to be the site of entrance of blood into the left pleural cavity. The tissues of the superior mediastinum were infiltrated with blood.

The heart weighed 380 gm. The aortic cusps were slightly thickened, but there was no separation of the commissures or interadherence of the cusps. The mouths of the coronary arteries were patent, with slight narrowing of the right coronary orifice. The upper fifth of the upper lobe of the left lung was voluminous, gray and crepitant. The remainder of the left lung was collapsed.

The entire thoracic aorta was dilated. At the junction of the arch and the descending aorta there was a sacular

ly normal structure. There was some increased vascularity. Sections of the arch were also normal. Sections obtained from the old aneurysm showed endarteritis with thickening of the adventitia. There was also perivascular infiltration with lymphocytes. There were scars and absence of elastic tissue in the media. These changes were considered as being consistent with a syphilitic process. The site of the acute rupture revealed normal margins, except for evidence of hemorrhage and infiltration by polymorphonuclear leukocytes of the layers between the intima and media. Section of the abdominal aorta revealed marked thickening of the intima and vascularization of the media below the atheroma of the intima.

The anatomical diagnoses were acute dissecting aneurysm

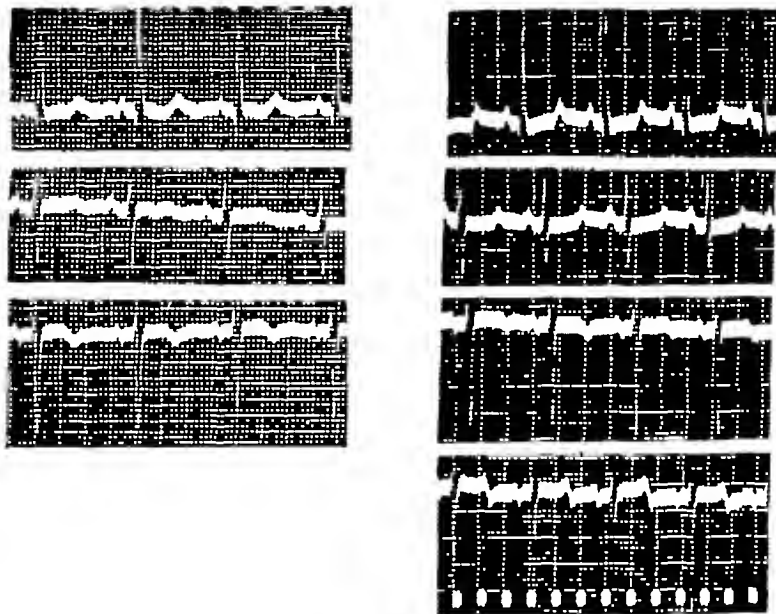

Figure 2 Electrocardiograms in Case 2 before (7/16/37) and after (8/10/37) the onset of dissecting aneurysm, reproduced in respective order

aneurysm, conical in shape and 6 cm in height, directed upward and posteriorly (Fig 3). The mouth of the aneurysm measured 5 cm in diameter, and its center was situated 8 cm from the origin of the left subclavian artery. The apex of the sac rested on the anterior aspects of the bodies of the second and third thoracic vertebrae, the latter of which was eroded to a depth of 1 cm. The aneurysm was almost completely filled with organized lamellated clots. The undilated part of the aorta at about the level of the center of the aneurysm was completely ruptured transversely. The margins of rupture were irregular. The mediastinal hematoma arose from this rupture. Beginning with the acute tear the aorta was dissected upward and downward between the media and adventitia. Downward the dissection ended at the level of the upper portion of the abdominal aorta. The intima of the aorta contained several atheromas from 0.1 to 1 cm in diameter. Some of these were calcified. At the junction of the old aneurysm and unruptured aortic wall along the margin of the rupture there was an area of softening 1.5 cm in diameter, which might have been the surface of the original rupture. The rest of the findings were irrelevant.

Histologic examination of the aorta revealed the following. Section of the ascending aorta showed essential-

ly normal structure. There was some increased vascularity. Sections of the arch were also normal. Sections obtained from the old aneurysm showed endarteritis with thickening of the adventitia. There was also perivascular infiltration with lymphocytes. There were scars and absence of elastic tissue in the media. These changes were considered as being consistent with a syphilitic process. The site of the acute rupture revealed normal margins, except for evidence of hemorrhage and infiltration by polymorphonuclear leukocytes of the layers between the intima and media. Section of the abdominal aorta revealed marked thickening of the intima and vascularization of the media below the atheroma of the intima.

DISCUSSION

A detailed description of the clinical course and of the functional and structural changes in dissecting aneurysm of the aorta has been given elsewhere.² As indicated, the condition should be considered as more than a medical "curiosity." The 10 cases previously reported occurred among 3206 necropsies, a ratio of about 1:320. Since this first report was published there have been, during the three years 1935 to 1937, inclusive, 11 additional cases among 2202 necropsies, a ratio of 1:200. It is of interest that in these 11 cases the condition was diagnosed 7 times clinically. The total number of correctly diagnosed cases available is about 15 since 1935, as contrasted with a total of 6 cases diagnosed up to that time.

of a larger group in the literature, failed to reveal such radiation without local dissection of the brachial artery.² Of 11 subsequent cases observed in the Boston City Hospital from 1935 to 1937, inclusive, there was only 1 in which radiation of pain occurred. This patient, a sixty-two-year-old man, had had attacks of precordial pain for two months prior to the onset of the dissecting aneurysm, which was characterized by aching pain in the chest, later radiating down both arms, into the penis and finally into both legs. The patient showed signs of vascular compression. The clinical diagnosis was dissecting aneurysm of the aorta with occlusion of the mesenteric, renal and iliac arteries. Postmortem examination confirmed the diagnosis of dissecting aneurysm. In addition, aortic stenosis caused by arteriosclerotic changes was found. It is possible that after the onset of dissection the presence of aortic stenosis interfered with the coronary flow, and that this was responsible for the character of the pain. Patients with aortic stenosis may have angina pectoris without coronary disease.

The features of Case 2 are even more unusual, and are of greater significance. The simultaneous occurrence of syphilitic and dissecting aneurysms seems to shatter the clinical axiom that syphilitic aneurysm speaks against the presence of dissecting aneurysm. The facts, however, that histologic examination revealed that the syphilis of the aorta was localized over the area involved by the old aneurysm, and that, contrariwise, syphilis was not present over the area of acute rupture, indicate that we are dealing with a rare case in which the two conditions coexisted. Hence, as in other cases, the acute rupture depended on arterial hypertension and on arteriosclerotic degeneration. Indeed, that the syphilitic inflammation induced a special resistance against the dissection is well demonstrated by the following facts: the dissection did not appreciably invade the old syphilitic aneurysmal wall, whereas it completely dissected the surrounding nonsyphilitic portion of the aorta, and in spite of the thinness of the old syphilitic aneurysm the dissecting aneurysm did not rupture over this area. This case therefore constitutes important direct evidence confirming our belief that the presence of syphilitic aortitis makes dissection difficult. Among the 300 cases of dissecting aneurysm analyzed by Shennan,¹ mainly collected from the literature, there were several in which the presence of syphilis was mentioned. The evidence for syphilis in

these cases, however, as is also stressed by Shennan, is insufficient. None of these cases had features similar to those of Case 2.

SUMMARY

1 Two cases of dissecting aneurysm of the aorta with unusual features are described, and reference is made to other cases which have been studied. In the first case, with electrocardiographic changes the dissection invaded the root of the aorta as well as the first portion of the left coronary artery, compressing the lumen of the mouth of this artery. This ischemia resulted in acute myocardial infarction. In the second case the patient suffered from arterial hypertension and from syphilis, and an old syphilitic aneurysm of the arch of the aorta coexisted with acute dissecting aneurysm originating near the opening of the syphilitic aneurysm. Histologic examination indicated that the syphilitic involvement was localized over the chronic aneurysm, while the area involved by the acute rupture contained an atheromatous softening without syphilitic changes. It is concluded that the two conditions occurred independently. The fact that the dissection invaded the syphilitic aneurysm but slightly, whereas it completely ripped the surrounding nonsyphilitic wall of the aorta, confirms the belief that a syphilitic process, through fusion of the layers of the aorta, tends to prevent dissection.

2 Among 2202 necropsies in the Boston City Hospital from 1935 to 1937, inclusive, dissecting aneurysm occurred in 11 instances, a ratio of 1/200. The condition was correctly diagnosed clinically in 7 of the 11 cases. Whereas but 6 cases had been recognized clinically up to 1935, the total number of correctly diagnosed cases now available from the literature is at least 21.

3 The differential diagnostic features of dissecting aneurysm and coronary thrombosis are discussed. Electrocardiographic changes may occur in dissecting aneurysm as a result of ischemia of the heart, due to acute blood loss, shock and pericardial tamponade, or, rarely, as a result of compression of the coronary artery.

The onset of dissecting aneurysm is characterized by sudden thoracic pain, transient syncope, dyspnea, orthopnea and prostration with circulatory collapse. Depending on the direction and the extension of the dissection, examination may reveal manifestations of mediastinal compression and tumor, partial or complete occlusion of arterial vessels and functional disturbances resulting from occlusion of the nutrient arteries, such as hemiplegia, paraplegia, monoplegia, intestinal paresis and infarction, hematuria and, at times, anuria. Tenderness and widening of the abdominal aorta may occur. As a result of rupture of the dissection, signs of fluid may develop over the chest, particularly over the left pleural surface, or the syndrome of cardiac tamponade may appear. Distortion of the aortic cusps may be the cause of diastolic murmur over this area in about 20 per cent of instances. In one case without pulmonary infarction jaundice developed, presumably as the result of hematoma.

Following the initial tear, thoracic pain often travels downward, and subsequently abdominal pain may develop. Frequently the signs of arterial compression change during the course of the disease. Fever and hemoptysis are often present after the onset of the rupture. In contrast to these manifestations, there are rare instances in which the onset is silent and the dissection is compatible with relatively good functional capacity. Development of an endothelial layer over the dissected surfaces of the aorta sometimes results in a true functioning double aorta.¹

It is obvious that the clinical course of dissecting aneurysm may closely resemble, and at times may be identical with, that of coronary thrombosis. The following are the main differences:

1. Whereas the onset of pain in dissecting aneurysm is usually sudden, the development of pain in coronary thrombosis is usually gradual and is often preceded by angina pectoris. In a smaller group thrombosis is preceded by attacks of pain of longer duration. The location of the pain of dissecting aneurysm is usually low substernal or in the mid-thoracic back. The pain does not radiate into the arm, except in rare instances, but is apt subsequently to travel, with the dissection, downward into the abdomen. The pain of coronary thrombosis, on the other hand, is not always mid-pain and usually radiates to the shoulders, arms, hands and other distant areas.

2. The chief characteristic features of the clinical course of dissecting aneurysm are compression of arterial and venous vessels, secondary manifestations of ischemia and hematoma of the aorta. These symptoms and signs often change from time to time. The vascular signs are apt eventually to

become more extensive, but in rare instances they clear up as a result of rerupture of the dissection into the main aortic channel, causing partial or complete re-establishment of the circulation.

3. Maintenance of high blood pressure occurs more frequently in dissecting aneurysm than in coronary thrombosis.

4. Aortic diastolic murmurs develop in dissecting aneurysm, but not in coronary thrombosis.

5. Pericardial friction rub is common in coronary thrombosis but relatively rare in dissecting aneurysm. In the latter condition the friction rub usually indicates beginning rupture of the dissection into the pericardial cavity, and therefore it is heard shortly before the onset of pericardial tamponade and death. Hence pericardial friction rub with relatively good peripheral circulation is distinctly in favor of coronary thrombosis.

6. Electrocardiographic changes with characteristic features of anterior or posterior infarction favor the diagnosis of coronary thrombosis.

7. Whereas the majority of patients survive attacks of coronary thrombosis, patients usually succumb to dissecting aneurysm of the aorta.

It is particularly fortunate that in both cases here reported electrocardiograms were obtained before as well as after the onset of the dissection. Until recently, few such observations were available on cases of dissecting aneurysm, and it has been generally held that the electrocardiogram is usually normal. Recently, Glendy and his associates² reported a case with electrocardiographic changes in Leads 2 and 3, which were suggestive of cardiac infarction of the posterior or diaphragmatic type. Postmortem examination in this case did not reveal myocardial infarction. The aortic dissection was found to extend proximally to the opening of the right coronary artery. Among the 11 cases observed in the past three years, electrocardiographic changes have been noted in at least 3 cases, in addition to those reported here. In these the dissection extended eventually into the pericardial cavity. The electrocardiographic changes are explained on the basis of cardiac anoxia, secondary to cardiac tamponade, to shock and to acute hemorrhage. The possibility of a certain degree of compression of the coronary arteries during life cannot be ruled out in these cases. The findings in Case 1 above indicate, however, that compression of the coronary artery as a secondary complication of dissecting aneurysm can in rare instances cause myocardial infarction. Hence electrocardiographic changes and coronary occlusion may be part of the picture.

It has been stated elsewhere that radiation of pain into the arm is rare in dissecting aneurysm. An analysis of 10 cases previously reported, as well as

is not definitely or exclusively an insurance risk, but had to be forced into this position by insurance. They admit that sickness insurance establishes a bureaucratic, organized, wholesale business in human misery, with central control and many branch establishments. They assert that social insurance is built on compulsion and on compensation against hazards, but compulsion leads to distrust, and regulation of risks leads to greed. Compulsion was necessary because only in this way was it possible to include broad sections of the population which were presumed to be in need of medical care but would not enter the system unless compelled to do so.

They have observed that sickness insurance has constantly restricted the direct relations between patients and physicians in private practice. Formerly there was a human relation which depended on confidence in the physician. Between the patient and his physician there is now a third party—the insurance carrier—and a fourth party,—the government,—a supervising bureaucracy which compels the physician to follow its regulations. Furthermore, these observers assert that if treatment does not bring the expected result the physician is discredited and is made punishable for every unavoidable failure.

Reports from countries having state-managed medicine state that the insured have not been satisfied with the new system. Restrictions of the means of healing have been offensive to them, they have looked on the contributions to the sickness-insurance system, taken from them through their employers by compulsion, as a retained share of their wages. They knew that they could obtain this retained money only in the form of insurance medical service or cash benefits, they believed they had been compelled to pay out money without receiving an equivalent, the only way in which the money or an equivalent could be recovered was to declare themselves sick and to meet the conditions set down by the law, this was an easy matter.

The reports continue with a criticism of the action of political parties which are using sickness insurance as the first step in the governmentalizing of all health care for the entire population. This point has not been reached, but it appears to be the objective.

Even in Europe some physicians have expressed the view that the idea of a free medical profession must not be abandoned, once it is completely abolished a cultural value will have been lost that cannot be replaced or restored. To physicians, human values are of greater importance than are political expedients.

These are only a few of the characteristics of systems of state managed medicine. All such systems

are not subject to the same criticisms, and those in some countries have been greatly improved since their inception by the continuous efforts of the medical profession of those countries.

Even at its best, do the American people and the American physicians want such a system? Before we wholly destroy our present plan of medical practice through revolutionary legislation, let us inquire carefully into the value of what we have and study searchingly the proposals of those who would take it from us, lest worse come in its place.

If there is truly any lack of good medical service for those who require it, the medical profession stands ready now, as it has invariably stood in the past, to supply that service. What other profession has ever developed such a tradition of sacrifice for the public welfare? It has been said that the rich and the poor get the best of medical care, and that the members of the great middle class suffer because they are unable to pay the costs of modern medical service.

The proponents and agitators for some radical change in the method of distributing medical services have made some serious and startling charges concerning the methods now in use. They continue to assert that 50 per cent of the population receives no medical care. A survey of some 38,600 persons made by the Committee on the Costs of Medical Care showed that 47.1 per cent had no illness over a period of more than a year. The study also showed that 47.9 per cent of these persons had the services of physicians. Only 5 per cent of the persons involved in the survey were presumably in need of medical services but for some reason did not avail themselves of medical care. Perhaps 5 per cent is not too large an estimate of those who because of human characteristics manifested as ignorance, stupidity or prejudice prefer cultism, patent medicines, the advice of friends or relatives or no medical service at all.

The medical profession today is conducting more social experiments in the methods of distributing medical services than all of the proponents for change have ever conducted. Out of the two hundred or more projects that are being studied or operated by county or state medical societies, it is hoped that methods may be found that can be utilized to supplement existing medical facilities wherever necessity demands.

These proponents and agitators have charged that the medical profession is static and obstructive. But without any compulsion from political or governmental sources, the profession has sought constantly to advance the standards of medical education, medical licensure and hospital practice, and is now making notable progress in the certifica-

A CHALLENGE TO MEDICINE

Rosco G. Leland, M.D.*

CHICAGO

RECENT social changes have been more numerous and radical than at any time in history. Among these developments are many new forms of medical practice which are a striking departure from the time-tested private practice of medicine. On many sides there appear reformers who urge even more drastic changes in the methods of distributing medical care, based on the pattern of foreign systems of sickness insurance. Thus far the medical profession in the United States has averted the entanglements, political domination and inevitable deterioration of medical service that would come from a system of compulsory sickness insurance.

The persistent propaganda of the proponents of socialized medical service has caused many physicians to doubt the future of medicine. A few are even exhibiting a fatalistic attitude in declaring that the socialization of medicine is inevitable.

Unfortunately, not many of those who write or speak in favor of socialized medicine clearly define the term. What is meant by it? Certainly not public health, for that phase of medicine has long been supported by taxation; certainly not the medical care of the indigent, for that is held to be a responsibility of local communities, to be paid for from tax funds, certainly not the institutional care of the mentally sick, the epileptic and the feeble-minded, for present methods appear to be the most appropriate for persons thus afflicted; certainly not the sanatorium management of tuberculosis, for this method has contributed much to the control of that disease; certainly not the medical practice actually required in the clinical phase of medical education, for this is a necessity in the training of physicians; certainly not workmen's compensation, for that system is now provided by statute and is state-supervised to varying degrees. The socialization of medicine, as the term is commonly used, refers to any form of medical advice, diagnosis and treatment provided, conducted, controlled or subsidized by the Federal or any state government, with the exceptions stated.

There are many views as to the type and extent of the social change proposed. There are those who advocate that all medical care should be provided through taxation; that is, physicians should

be state employees. Others urge some form of sickness insurance—voluntary or compulsory.

Voluntary sickness-insurance systems are usually the precursors of compulsory systems. No country has ever operated a system of complete state medicine in which all medical services were financed by physicians who derived their sole income from the state, but many countries have adopted some system of sickness insurance. All these systems may be included in the term "state-managed medicine." No value can be derived from criticism of a country for having adopted a system of state-managed medicine, but a critical analysis of the systems themselves may be helpful in determining whether such methods are preferable to the free and independent practice of medicine such as exists in the United States.

A careful examination of the systems of state-managed medicine reveals the following conditions:

1. There is no decrease in the cost of medical care. Indeed, the system costs a staggering cost of maintenance.
2. Public health and preventive medicine are neglected or abandoned. State-managed medicine does not provide the annual health examinations or the immunizations usually provided before the system was adopted.
3. Morbidity and mortality are not reduced.
4. The problem of so-called chronic diseases is aggravated.
5. Neuroses are created.
6. Overmedication is encouraged.
7. The burden of the system is distributed over the whole income class, which is least able to bear it.
8. Medical care for the indigent is curtailed.
9. The medical profession is divided into a "first" and a "second" class.
10. Graduate education is not encouraged and is usually neglected.
11. The hospital load is increased. Hospitals are encouraged to practice medicine.
12. Attention and financing are concentrated on the less essential health and medical measures.
13. Diagnosis and treatment are mechanical and superficial.
14. Professional associations are compelled to devote their energies to the defense of medicine against non-medical and political interference rather than to scientific and educational services.
15. Medical service becomes a political issue.
16. Control over medical service is placed in the hands of unqualified, non-medical authorities and organized as such.
17. The road is closed to the use of more efficient methods.

Some European medical observers are now politer than formerly in criticizing their systems of state-managed medicine. They are seeing that sickness

*President of the American Society of the American State Medical Society, and President of the American Medical Association, 1935-1936.

Director of the Bureau of Medical Research, American Medical Association, Chicago.

is not definitely or exclusively an insurance risk, but had to be forced into this position by insurance. They admit that sickness insurance establishes a bureaucratic, organized, wholesale business in human misery, with central control and many branch establishments. They assert that social insurance is built on compulsion and on compensation against hazards, but compulsion leads to distrust, and regulation of risks leads to greed. Compulsion was necessary because only in this way was it possible to include broad sections of the population which were presumed to be in need of medical care but would not enter the system unless compelled to do so.

They have observed that sickness insurance has constantly restricted the direct relations between patients and physicians in private practice. Formerly there was a human relation which depended on confidence in the physician. Between the patient and his physician there is now a third party—the insurance carrier—and a fourth party,—the government,—a supervising bureaucracy which compels the physician to follow its regulations. Furthermore, these observers assert that if treatment does not bring the expected result, the physician is discredited and is made punishable for every unavoidable failure.

Reports from countries having state-managed medicine state that the insured have not been satisfied with the new system. Restrictions of the means of healing have been offensive to them, they have looked on the contributions to the sickness insurance system, taken from them through their employers by compulsion, as a retained share of their wages. They knew that they could obtain this retained money only in the form of insurance medical service or cash benefits, they believed they had been compelled to pay out money without receiving an equivalent, the only way in which the money or an equivalent could be recovered was to declare themselves sick and to meet the conditions set down by the law, this was an easy matter.

The reports continue with a criticism of the action of political parties which are using sickness insurance as the first step in the governmentalizing of all health care for the entire population. This point has not been reached, but it appears to be the objective.

Even in Europe some physicians have expressed the view that the idea of a free medical profession must not be abandoned, once it is completely abolished a cultural value will have been lost that cannot be replaced or restored. To physicians, human values are of greater importance than are political expedients.

These are only a few of the characteristics of systems of state managed medicine. All such systems

are not subject to the same criticisms, and those in some countries have been greatly improved since their inception by the continuous efforts of the medical profession of those countries.

Even at its best, do the American people and the American physicians want such a system? Before we wholly destroy our present plan of medical practice through revolutionary legislation, let us inquire carefully into the value of what we have, and study searchingly the proposals of those who would take it from us, lest worse come in its place.

If there is truly any lack of good medical service for those who require it, the medical profession stands ready now, as it has invariably stood in the past, to supply that service. What other profession has ever developed such a tradition of sacrifice for the public welfare? It has been said that the rich and the poor get the best of medical care, and that the members of the great middle class suffer because they are unable to pay the costs of modern medical service.

The proponents and agitators for some radical change in the method of distributing medical services have made some serious and startling charges concerning the methods now in use. They continue to assert that 50 per cent of the population receives no medical care. A survey of some 38,600 persons made by the Committee on the Costs of Medical Care showed that 47.1 per cent had no illness over a period of more than a year. The study also showed that 47.9 per cent of these persons had the services of physicians. Only 5 per cent of the persons involved in the survey were presumably in need of medical services but for some reason did not avail themselves of medical care. Perhaps 5 per cent is not too large an estimate of those who because of human characteristics manifested as ignorance, stupidity or prejudice prefer cultism, patent medicines, the advice of friends or relatives or no medical service at all.

The medical profession today is conducting more social experiments in the methods of distributing medical services than all of the proponents for change have ever conducted. Out of the two hundred or more projects that are being studied or operated by county or state medical societies, it is hoped that methods may be found that can be utilized to supplement existing medical facilities wherever necessity demands.

These proponents and agitators have charged that the medical profession is static and obstructive. But without any compulsion from political or governmental sources, the profession has sought constantly to advance the standards of medical education, medical licensure and hospital practice, and is now making notable progress in the certifica-

tion of specialists. To a remarkable degree these objectives are being accomplished. Today both curative medicine and preventive medicine have advanced to new and higher planes of efficiency. The profession is constantly perfecting methods of diagnosis and treatment, there has been a striking reduction in the prevalence of certain communicable and infectious diseases, infant mortality has been greatly reduced, and in the past century life expectancy at birth has been increased from twenty-eight years to almost sixty.

These meddlers with medical practice assert that present methods in the United States are costly and inefficient. In countries having state-managed medicine, there are as many bureaucratic employees as there are physicians giving medical service. State-managed medicine imposes such extensive red-tape, record-keeping and political interference, dominance and control on the physicians practicing under the system that they cannot devote the time they should to the actual practice of medicine. Loading the system with unnecessary bureaucratic personnel and with political meddling and direction tend to increase the cost of medical service and at the same time to reduce its quality.

It is claimed by the supporters of social reform in medicine that state-managed medicine will raise the standards of medical practice, deal a death blow to cultism and quackery and encourage preventive medicine and immunization. Standards of medical practice have advanced faster in the United States with free and independent medical practice than in any country having state-managed medicine. Germany, after fifty-four years of sickness insurance, is the happy hunting ground for quacks. It is the only nation to give official recognition and endorsement to all forms of quackery. Preventive medicine in the United States is the envy of the medical profession in many foreign nations.

The medical profession has always been its own most severe critic, and notwithstanding the advances that have been made toward a better understanding of disease and its control, it recognizes that there are some conditions and practices that should be corrected. For example, there are areas in which there seems to be an uneven distribution of physicians and other medical facilities, and in which the evils of contract and corporation practice should be corrected, the alleged abuse of clinic and hospital facilities should be investigated, the unwarranted practice of medicine by boards of health and boards of education eliminated, the medical phase of workmen's compensation improved and the dangers in group hospitalization recognized and averted.

In all these and many other problems confronting medicine, there are both ethical and economic

dilemmas. The fundamental concept in both ethics and economics is that of value. In economics the ultimate test of value is the amount of goods which will be consumed or the medium of exchange which will be paid in the market. Ethics embraces a wider conception, and makes as its ultimate test of value the effect on the individual and on the society in which he lives. Medical ethics deals with direct individual and personal services between whole personalities. Medical relations cannot exist between an oculist and an eye, a corporation and a broken law, a hospital and a disease, a laboratory and a blood specimen or an insurance policy and a compensation case. If medical relations are to be ethical—that is, in furtherance of the ultimate good health of the patient—they must be between the patient who is to be treated and the physician, trained according to established standards and having access to the accumulated knowledge of the ages.

To combat the agitation for drastic changes in medicine, the medical profession must continue to practice good medicine. It has been accused of being individualistic. This criticism should be accepted as a compliment insofar as the diagnosis, treatment and close personal confidential relations of private practice are concerned. Physicians must continue to be individualistic and ethical in their private ministrations to maintain health and to alleviate sickness. But they must speak and act collectively on matters pertaining to economics, public relations, legislation, the preservation of professional ideals and traditions, and the maintenance and advancement of medical ethics and the standards of medical education and practice.

There is within the medical profession in the United States a small but loudly vocal minority which would hasten the advent of some form of state-managed medicine, with all its methods of mass production, assembly-line technic and political dominance and control. These few physicians do not speak for the vast majority of substantial and representative physicians who cherish the free and independent practice of ethical medicine. This noisy minority does, however, appeal to and has the support of a group of non-medical propagandists and agitators who see in a system of state-managed medicine an opportunity for position, power and plunder. A few physicians whose acts and statements are filled with scorn, ridicule and derision for the ideals, traditions and ethics of medicine must not be permitted to speak for reputable and substantial physicians who believe in the institution of ethical medicine.

Quacks are abroad plying their trade in the realms of economics, sociology and ethics as well as in the field of medicine. Large groups of people

under the stimulation and leadership of these extremists and self-styled experts are assuming to know that which they do not know. They are contemptuous of the experiences of the past, they decry special skill, they substitute rhetoric for reason. The large and representative group of ethical physicians have an obligation to unite solidly in sentiment and in action against the utterly false representations of the reactionary, radical, self-styled experts who would destroy medical values that have required generations and centuries of accumulated scientific effort and experience to acquire.

The medical profession has not discharged its entire obligation to society by healing the sick or preventing disease. Its broader obligation lies in a concerted determination and effort to preserve that form of practice which best conforms to good public policy and which will perpetuate the free, independent, scientific and ethical institution of medicine.

The important question is this

Shall medicine continue to be practiced by men and women who are scientifically trained and who are devoted to the relief of suffering humanity, or shall the practice of medicine be taken over by a group of medically untrained bureaucrats who will use the medical profession as a tool and the sick as clay in moulding a huge political machine?

The obligation of the medical profession seems clearly defined. It must vigorously resist all efforts that are likely to provide sick people with the mere dregs of medical service, or that are destined to reduce medicine to the serfdom of science.

Now that the economic phase of medical practice is demanding more consideration, ethical relations must not be forgotten or removed from the central position they have always held. On the contrary, economic relations and plans, just as much as professional services and conduct, must be tested by the principles of medical ethics. Medical ethics is not outgrown or antiquated, it must continue to be vital, elevating, dominating and enduring through continual respect and adherence.

When physicians become, if they ever should, mere robots, making diagnoses from card indexes and mechanical gadgets and prescribing treatment from prepared and numbered labels, and when patients become a mere collection of interesting human parts to be shunted from one corner to another of a medical repair shop for some heartless and pseudoscientific tinkering, America will have lost one of its greatest institutions,—free and independent medicine,—and the American people will have lost some of their most valuable human traits, namely confidence in, respect for, and reliance on the scientific men and women who protect their health and prolong their lives.

PRIMARY THROMBOSIS OF THE AXILLARY VEIN

BERNARD I. GOLDBERG, M.D.,* AND JOHN A. FOLEY, M.D.†

BOSTON

THROMBOSIS of the axillary vein following strain (effort) has been comprehensively described by Matas.¹ Primary or idiopathic thrombosis occurring spontaneously is rare. We report below a case in which no etiology could be found and in which studies by means of an opaque medium visualized the obstruction.

CASE RECORD

C. F. M., aged 32, married, was admitted to the Boston City Hospital on May 4, 1935. Two weeks before admission he had had an upper respiratory infection accompanied by a slight cough, which cleared up in the course of a week. He was not incapacitated and aside from a healing herpes simplex on his upper lip there were no residual effects. Five days prior to admission the patient felt some discomfort in the left shoulder. There was, however, no spontaneous pain or pain on motion, and no areas of tenderness were present. This condition per-

sisted for about 3 days. Two days before entry the patient noted that his left upper extremity felt heavier and appeared larger than his right. He reported to the Out-patient Department of the Boston City Hospital, where the condition was diagnosed as venous thrombosis. X-ray photographs were taken, and the patient was sent home to rest. He was seen at home by one of us (J. A. F.), who sent him to the hospital.

His past history was important only in that he had indulged in alcohol quite freely at times. The family history was noncontributory. The patient was an electrician's helper by occupation. He was right handed.

Physical examination showed a robust young man whose general condition was entirely normal except for the findings revolving around his complaint. The neck showed no adenopathy, the thyroid gland was not palpable, and there were no abnormal pulsations. The lungs were clear and resonant throughout, there were no rales or abnormal breath sounds. The heart showed no murmurs or thrills, and the rhythm was regular. There was no displacement of the cardiac dullness. The lower extremities showed no varicosities.

The left upper extremity was larger in circumference than the right, and the skin was colder and darker. There was a definite increase in the number of visible superficial

*From the Fifth Medical Service, Boston City Hospital and the Department of Medicine, Boston University School of Medicine, Boston.

Assistant professor of medicine, Tufts College Medical School junior visiting physician, Boston City Hospital.

†Professor of clinical medicine, Boston University School of Medicine; physician-in-chief, Fifth Medical Service, Boston City Hospital.

veins, and the veins were much more prominent than in the right extremity. Palpation of the left axillary vein was accompanied by a slight degree of tenderness. The vein presented a typical cord like tumefaction. There were no changes in the reflexes, and no motor or sensory changes. The radial, brachial and axillary arteries were easily palpable. On the anterior thoracic wall many dilated venules were visible, and the skin of the upper half of the thorax anteriorly on the left side seemed slightly darker than the skin elsewhere.

The laboratory findings were as follows. The urine had a specific gravity of 1.027, with no albumin and no sugar,

Figure 1

the sediment was negative. The hemoglobin was 74 per cent. The red-cell count was 4,500,000, and the white-cell count was 8000, with 68 per cent polymorphonuclears, 21 per cent lymphocytes, 5 per cent monocytes, 3 per cent eosinophils and 3 per cent basophils. The blood Kahn test was negative, and the nonprotein nitrogen was 27 mg per cent. A blood culture showed no growth.

A tentative diagnosis was made of thrombosis of the axillary vein, with a suspected mediastinal mass on the left side or possibly a cervical rib.

Visualization of the vein was undertaken in order to rule out the possibility of pressure by an obscure mass, to locate the site of obstruction, to note changes in the contour of the distal portions of the vein, and to observe the nature of the collateral channels. For outlining the course of the vein we first used Skiodan. The injection

was carried out in the x-ray department and the films were taken during the injection. The injection, which was done about 2 weeks after the onset of the symptoms, was reported as follows: "Examination of the left upper arm after the injection of Skiodan [Fig 1] in the ante cubital vein shows a portion of the brachial and the axillary vein outlined. The brachial vein is considerably narrowed and one of the valves is markedly dilated. The collateral branches cannot be traced. These findings are consistent with thrombosis of the brachial and axillary veins. An infrared photograph taken at this time demonstrated the venous collaterals in the arm and chest (Fig 2)."

Following his discharge from the hospital, this patient resumed his occupation and has worked without interruption. He has never noted any swelling or pain, or

Figure 2

indeed any symptoms referable to his arm. Subsequent examinations showed no special prominence of the veins on the left upper or lower arm as compared with those on the right. Tests for hydrostatic effects were negative, and measurements revealed no material difference.

This patient was last seen 14 months after leaving the hospital. On this occasion he reported that he was still free from symptoms. The examination of the extremity and a general physical examination were both negative, so that on the basis of clinical findings there was nothing to indicate any alteration in the circulatory function of the affected arm. At this time an x-ray film (Fig 3) taken after the injection of 10 cc of Hippuran showed the entire axillary vein well outlined, its caliber slightly larger and some of the branches partially outlined. One of the branches of the axillary vein could be traced. The valves were not so dilated as they had been at the previous examination. There were no changes in the humerus or in the surrounding soft tissue.

In general, cases of axillary thrombosis fall into one of three groups. The first comprises those sec-

We are indebted to Dr. Edward A. Edwards for the infrared photograph.

ondary to intravascular or extravascular inflammatory processes or extravascular pressure from contiguous neoplasms or enlarged nodes. The second group comprises cases resulting from a sudden strain or other trauma. In the third group are included a small proportion of cases which in the absence of any known trauma must be classified as idiopathic, yet in these it is impos-

Figure 3

this apparent paucity, the impression prevails that many cases have never been reported. This applies particularly to the American literature. Cases of primary thrombosis of the idiopathic type have proved even rarer.

The mechanism of the development of the condition remains obscure, and many theories have been developed to account for it. Von Schrötter,³ who reported the first case, regarded it as a localized phlebitis resulting from the sudden traumatic stretching and compression of the vein. Subsequent studies led to the theory that the trauma occurred between the clavicle and the first rib, with the costocoracoid ligament and the subclavius muscle as contributing factors. Slowing of the circulation, rupture of the subclavioaxillary valve, venospasm induced by sympathetic irritation of traumatic origin, a tear in the wall of the vein—these and several other factors have been invoked. The reader is referred to the exhaustive articles by Matas¹ and Veal and McFetridge⁴ for a complete discussion of this subject. The lack of autopsy material has proved a distinct handicap in determining the pathogenesis.

Veal and McFetridge⁴ studied the problem both in the living subject and in fresh autopsy material. They report 2 cases of primary thrombosis. They approached the subject by vasographic studies on normal subjects, using Thorotrast (colloidal thorium dioxide) as the opaque medium. They noted that anatomical relations changed when the factor of movement was introduced; the axillary vein was capable of accommodating itself to moderate changes in position. On hyperabduction and external rotation, there was a compression of the vein as the subscapularis muscle came to lie between the vein and the head of the humerus. They determined that the obstruction occurred at the point where the vein passed over the subscapularis muscle in the position of hyperabduction and external rotation. In this position the emptying time was shorter rather than longer. Additional observations demonstrated that the important factor in raising the venous pressure is not the position of the arm, but rather the increased thoracic pressure which is caused by coughing or straining.

COMMENT

The absence of an etiologic background has forced us to assume that the case herein reported belongs to the rare group of idiopathic or primary axillary thrombosis. The patient was known to have indulged freely in alcohol, but no alcoholic bout preceded the onset. It is doubtful whether alcoholism per se plays any role other than through

sible to rule out trivial trauma or, as Matas terms it, 'banal' trauma. The second and third groups are characterized by the sudden development of edema, pain in the affected extremity, varying degrees of cyanosis, and a palpable cord-like mass, often tender, representing the axillary vein.

The literature concerning axillary thrombosis caused by strain was adequately reviewed by Matas¹ in 1934. Paggi's² survey resulted in the collection of only 74 reported cases up to July, 1933. Despite

the traumatism that may accompany it. We have admitted annually to our service approximately 850 patients with acute alcoholism, some in a severely toxic state. The rarity of axillary thrombosis among these individuals goes to prove that alcoholism plays no direct part in the etiology of this disease.

Along with the distinctive characteristics typifying the condition in our case, there were several atypical features. The onset was gradual, and was unaccompanied by pain. The edema was also relatively slow in development. There was only slight tenderness on palpation of the vein. The patient was right-handed, and the left axillary vein was the seat of thrombosis.

SUMMARY

An additional case of primary thrombosis of the axillary vein is reported. We have placed this in the idiopathic group because of the absence of trauma or any other inciting cause. Vasography revealed the site of the thrombosis. A follow up vasogram taken fourteen months later still showed some radiographic deviation from the normal.

REPORT OF TWO CASES OF BOTULISM IN MASSACHUSETTS

HENRY ROSEN, M.D.,* AND NATHAN GORDON, MD†

BOSTON

DURING the period 1899-1935, botulism has been reported only six times in the New England States.¹ Only once in the United States has it been reported as being acquired through the ingestion of home-canned mushrooms. It is of interest, therefore, to report 2 such cases which occurred recently in Cambridge.

Case 1. C. P., a 48-year-old man, on January 16, 1937, ate some wild mushrooms which had been picked 6 months before in the woods of a nearby suburb and canned at home. Previously, the home-canned mushrooms had always been reheated before being served. This time, however, they were not. No effect was noted that day or the next, when the man again ate a jarful of these mushrooms, unheated. On January 18 he arose with a dizzy headache, and was nauseated and unable to see distinctly. He went to work, but soon returned home because of his inability to see what he was doing. There was no vomiting, and he had no bowel movement that day. His tongue felt stiff, he could not swallow well, his speech became thick, and he then began to see double. At this point he was sent to the Cambridge Hospital by Dr. J. P. Nelligan, of Cambridge, with whose permission these cases are presented.

Physical examination revealed a well-developed and well-nourished adult male, rational and co-operative but slightly drowsy, and complaining of blackness before his eyes. The temperature was 97.2° F., the pulse 60 and the respirations 20. The blood pressure was 110/70. Paralysis of all the ocular muscles was present. Print could not be read, the patient stating that he saw double. The optic disks were pale. The face was slightly puffed out on the right side. The tongue and jaw were deviated to the right. The palatal reflex was absent. The speech was thick and slurring and the enunciation of words was impaired. There was difficulty in swallowing, with regurgi-

tation of fluids through the nose. The breath was foul. There was no stiff neck. Generalized muscular weakness was present. Tendon reflexes were exaggerated. The abdominal reflexes were absent, the Babinski response was present bilaterally, but there was no Kernig or clonus.

The patient grew worse while on the ward, he was totally unable to swallow, choking and gagging when taking fluid and regurgitating it through the nose. The speech became mumbling. His mind remained clear at all times.

The urine gave an acid reaction and had a specific gravity of 1.026, it contained no sugar or albumin but showed a 2+ acetone reaction, the sediment was negative. The white-cell count of the blood was 5100, and the red-cell count 3,280,000. The hemoglobin was 62 per cent (Sahlb). A blood Hinton test was negative. The spinal fluid had an initial pressure equivalent to 170 mm of water, dynamics were normal. The fluid was clear and colorless and no cells were found, the total protein was 29 mg and the sugar 77 mg per 100 cc.

A clinical diagnosis of botulism was made, botulinus antitoxin was sought, but could not be obtained until the following morning. In the meantime 1/4 gr. of morphine was given every 4 hours, and a hypodermoclysis of 1500 cc. normal saline and 5 per cent glucose was administered. Then 20,000 units of a polyvalent botulinus antitoxin (Lederle—labeled "for use in animals") was given intravenously at regular intervals over a 12 hour period, the patient first being tested for serum sensitivity. He was then transferred to the Boston City Hospital and placed in a respirator because of beginning respiratory distress. However, this complication cleared within 1 day. At that hospital he received an additional 115,000 units of the polyvalent antitoxin in divided doses at regular intervals. Clyses and intravenous solutions of 3000 cc. of fluid were given daily. Serum sickness developed a week later and soon cleared up. The paresis of the larynx and pharynx continued until the 12th day after entry, when the patient began to swallow small amounts of fluid. From then on he took his own nourishment. The cranial nerve palsies subsided. He slowly regained

Shaw Sanatorium Akron Ohio

strength and at the time of discharge it had returned to a remarkable degree, although there was considerable generalized wasting of subcutaneous tissue. On February 13, or 26 days after the onset of the disease, he was discharged improved.

When seen 9 months later, he had completely recovered

Case 2 M. P., aged 43, the wife of the patient in Case 1 was admitted to the Cambridge Hospital on January 20, 1937, with a history of nausea, difficulty in swallowing, weakness and blurred vision of 1 day's duration.

Four days before entry she ate a small amount of the above mentioned home-canned mushrooms which had not been reheated. She was well for 3 days, or until January 19, when she began to feel nauseated, became weak, and developed progressive difficulty in swallowing and blurring of vision. She was then sent to the hospital.

On admission the temperature was 97°F, the pulse 115, and the respirations 20. The blood pressure was 160/100. Physical examination revealed a flushed face, unsteady gait and nasal speech. The patient continually cleared her throat in an attempt to get rid of the mucus. There was a right-sided facial palsy of peripheral type. She was unable to read print because of blurred vision. The eyes showed a partial paralysis of all the extrinsic ocular muscles. Both optic disks were pale. The breath was foul, the tongue was coated and deviated to the right. The palatal reflex was absent. There was a marked inability to swallow, and attempts to take fluid caused gagging and choking. The neck was slightly rigid. The heart and lungs were negative. There was marked weakness of the arms and legs. Abdominal reflexes were absent on the left, and a Babinski response was present on the left, but there was no clonus or Kernig.

On January 20, the urine showed an acid reaction and a specific gravity of 1.016. There were no sugar and no albumin, but a heavy trace of acetone. The sediment was negative. The white-cell count of the blood was 14,000, with 85 per cent polymorphonuclears, 12 per cent lymphocytes and 3 per cent monocytes. The red-cell count was 4,500,000, and the hemoglobin 85 per cent (Sahli).

The patient could take nothing by mouth for the next 3 days, and received 3000 cc. of fluids intravenously and by clysis each day. A total of 50,000 units of polyvalent botulinus antitoxin was administered in the following doses: 5000 units in divided amounts was given in the 1st hour intravenously, the next morning 25,000 units was given with the clyses and intravenous infusions, that afternoon 5000 units was given intramuscularly, the third day 10,000 units was given with the clyses, and on the 4th day, when definite improvement had been noticed, only 5000 units was given with the clyses.

By that time the patient's vision had improved to the extent that she could read print, the nasal tone of the voice was markedly lessened, and she no longer kept clearing her throat. Her eye condition remained about the same, but the palatal reflex returned, and she was able to swallow small amounts of fluid without choking or regurgitating through the nose. The Babinski response became equivocal.

From then on she steadily improved, except for a serum reaction which developed on January 27, and was successfully treated by adrenalin and magnesium sulfate and calcium lactate by mouth. Her weakness gradually disappeared, and the gait soon improved and became normal. On discharge, February 6, or 18 days after admission, she showed only a very slight residual weakness of the eye muscles.

The patient was completely recovered 9 months later.

Attempts to prove the presence of the botulinus bacillus or its toxin were unsuccessful. Unfortunately there was no sample of the unheated mushrooms of the first jar from which both patients had been served. Some mushrooms from another jar were found in a garbage can on January 21. These and an unopened jar were sent to the Bacteriology Department of the Tufts College Medical School, and also to the Antitoxin and Vaccine Laboratory of the Massachusetts Department of Public Health. Cultural and animal inoculation tests were negative for *Clostridium botulinum* or its toxins, hence only a clinical diagnosis of botulism could be made.

DISCUSSION

The early recognition of botulism is very important, so that antitoxin may be administered promptly. Botulism is an acute poisoning caused by the toxin of *Clostridium botulinum*.² The bacillus is essentially a soil organism and is found in dust, dirt, carrion, fruit, vegetables and plants. Under anaerobic conditions the growing bacillus produces a thermolabile poisonous toxin, which when ingested affects primarily the cells of the central nervous system. Mushrooms, the food ingested in these cases, have only once been reported as the carrier of the bacillus or its toxin. Botulism should be seriously considered in every case of poisoning caused by the ingestion of canned mushrooms.

The incubation period usually varies from eighteen to thirty-six hours after ingestion of the toxin, but symptoms may occur as early as two hours and as late as eight days after.³ The period was

Table 1 Signs and Symptoms of Botulism

Subnormal temperature	+	+
Slow pulse	+	—
Disturbance of respiration	+	—
Mental alertness	+	+
Absence of vomiting and diarrhea	+	+

forty-eight hours in Case 1 and seventy-two hours in Case 2. Early constipation, an outstanding symptom of botulism, was present in both patients. Disturbance of vision was caused by paresis of the ocular muscles, and was a prominent symptom. Fatigue, with vertigo and headache, was soon followed by generalized muscular weakness, this being the usual course of the disease. Loss of the light reflex, which may or may not occur, was not present. Within a short time there was a

paresis of the pharyngeal and lingual muscles, producing difficulty in swallowing with regurgitation through the nose, and difficulty in talking. This group of symptoms is very common in botulism. The absence of sensory disturbances, diarrhea and vomiting, and the presence of mental alertness, subnormal temperature and a slow pulse in our patients corresponded unusually well with the textbook description of the disease.

The duration of the disease varies from two to twenty-six days. When recovery occurs, convalescence is slow and tedious. Disturbance of vision is usually the last symptom to disappear, and may persist for months. There seems to be no permanent severe disability after recovery. Where death occurs, it is usually caused by a terminal bronchopneumonia or by respiratory paralysis.

The differential diagnosis includes mushroom poisoning, bulbar poliomyelitis, encephalitis and food infection. Mushroom poisoning had to be ruled out first in these cases. In botulism the incubation period is long, because the bacillus produces a toxin which mediates its symptoms through the central nervous system, while in mushroom poisoning the period is much shorter, the poison directly affecting the gastrointestinal tract, with subsequent vomiting, diarrhea and abdominal cramps. The latter poison may also produce nephritis with anuria or hemoglobinuria, mental confusion, excitement and convulsions, and excessive perspiration and lacrimation. Bulbar poliomyelitis and encephalitis were seriously considered, but in view of the fact that the spinal fluid findings were entirely negative, they also were ruled out. Food infection (so-called ptomaine poisoning) was ruled out by the absence of gastrointestinal symptoms such as vomiting, diarrhea and abdominal cramps, by the absence of fever, and by the presence of marked disturbance in the central nervous system.

Meyer¹ quotes Velikanoff⁴ as showing that in a series of 194 Russians poisoned by botulinus toxin 119 were treated with antitoxin and 24,

or 20 per cent of those treated, died. Seventy of the 75 untreated cases died, a mortality of 93 per cent. In the experience of the Russian observers, one may expect a reduction in the mortality of botulism provided the antitoxin is administered within the first seventy-two hours after ingestion of the botulogenic food. Large doses should be administered early either by intramuscular or intravenous route, the latter being preferable. Case 1 received 135,000 units without harmful effects other than a mild serum reaction.

Supportive treatment consisting of 5 or 10 per cent glucose in normal saline solution by clysis or intravenous route is an important measure. Rosenau² states that the patient should be kept under the full influence of morphine until the antitoxin is obtained, for in the experimental disease this opiate delays the action of the toxin. The stomach should be washed out and the bowels purged with an active cathartic. A respirator should be available in case of respiratory failure.

SUMMARY

1 Two cases of botulism, clinically diagnosed and following the ingestion of home-canned mushrooms, are reported. Recovery took place in both cases, polyvalent botulinus antitoxin being administered within seventy-two hours after ingestion of the food, and twenty-four hours after the onset of the symptoms.

2 Only 6 cases of botulism have been reported in New England in the period 1899-1935, and in the same period only 1 case in the United States has been attributed to eating mushrooms.

3 Early recognition of the disease, with prompt administration of the antitoxin, is important in reducing the mortality.

ANAPHYLAXIS TO SODIUM MORRHUATE FOLLOWING
INJECTION TREATMENT OF INTERNAL HEMORRHOIDS

NATHANIEL J SIMMONS, M D *

BOSTON

SINCE the introduction in 1929 of sodium morrhuate as a sclerosing agent, it has attained considerable popularity in the treatment of varicose veins, hydroceles, olecranon and prepatellar bursitides and internal hemorrhoids. The purpose of this paper is to report 2 cases of constitutional anaphylactic reactions which have occurred following its use in the injection of internal hemorrhoids. Probably many other such reactions which have taken place have not been reported. They constitute a distinct hazard, and should be guarded against.

In reviewing the literature we find that Cooper¹ in 1933 reported a mild dermatitis with an annoying pruritus following the use of 10 cc of a 5 per cent sodium morrhuate solution.

Allergic-like reactions to this agent when employed for the obliteration of varicose veins have been reported by Zimmerman² and Lewis.³ Praver and Becker⁴ from their dermatologic clinic reported untoward reactions in 7 out of 126 patients who received 783 injections of a 5 per cent solution.

According to Haines,⁵ the mechanism of its action is somewhat obscure, and no criteria as to what constitutes sodium morrhuate have been laid down. He states that some commercial samples were analyzed, with a view to ascertaining the degree of uniformity attained by various manufacturers. Examination disclosed considerable differences between the solutions: some were clear at room temperature, while others were turbid or gelatinous or contained a crystalline sediment. The solutions were analyzed for the content of fatty acids and for their iodine value. It was found that sodium oleate is both more toxic and less active as a sclerosing agent than are the sodium salts of the more highly unsaturated fatty acids. The iodine value rises as the elimination of oleic acid from the unsaturated fraction becomes more complete.

Sodium morrhuate is a mixture of the sodium salts of the unsaturated fatty acids occurring in cod-liver oil, and it is thus impossible to give its chemical formula. Originally, the name "morrhuc acid" was given by Gautier and Mourges to a nitrogenous putrefaction product, hydroxydihydropyridine butyric acid ($C_9H_{13}NO_3$), found in rotted cod-liver oil, but this term is now applied to

the product obtained following the hydrolysis of purified cod-liver oil. This impure morrhuc acid is then neutralized with caustic soda, and is further purified by partial fractionization in order to give a sodium morrhuate suitable for medicinal use.

Zimmerman² has raised the question whether the saponified fatty acids themselves are capable of producing an allergic reaction, or whether the latter is due to an admixture with liver protein. Another theory which has been offered is that hemolysis may occur, the contact of the patient's blood with the solution resulting in liberation of protein substances which are responsible for the reaction. Still another theory, advanced by Lewis,³ is that sodium morrhuate may act as a hapten and sensitize susceptible individuals, particularly if they have received an injection one or two weeks before.

I have used a 5 per cent solution of sodium morrhuate in the injection of large internal hemorrhoids in 75 cases. In 2 cases in this series severe constitutional anaphylactic reactions were noted, and are here reported.

Case 1 Mr W, aged 30, was seen on February 14, 1937, and gave a history of bleeding from the rectum for 3 months. Palpation of the anus and rectum disclosed no new growths, polyps, fissures or fistulas. Proctoscopic examination brought into view a ring of internal hemorrhoids. Sigmoidoscopic examination to a depth of 23 cm. was negative. One cubic centimeter of a 5 per cent solution of sodium morrhuate was injected about the posterior right internal hemorrhoid. The plunger of the syringe was withdrawn before the injection was started in order to make sure that the needle did not enter a vein. No untoward reaction occurred.

One week later 1 cc. of sodium morrhuate was injected, this time into the region of the posterior left internal hemorrhoid. The patient immediately complained of feeling ill and very warm. He also felt dizzy and nauseated. He paled markedly, perspiration became profuse and the respirations shallow, the pulse was imperceptible, and the blood pressure dropped to 60/0. A subcutaneous injection of 1 cc. of a 1:1000 adrenalin solution was given immediately. Spirits of ammonia were also administered. The attack lasted for 20 minutes. After resting for about 1 hour he was allowed to return to his home. He reported that he felt badly for 2 days following the injection. The suddenness and severity of this attack, as well as the danger of immediate death, showed the advisability of using another sclerosing solution for this patient.

Case 2 Miss K., aged 22, was seen on May 10, 1937 and complained of profuse bleeding from the rectum and rectal prolapse. Proctoscopic examination brought into view large internal hemorrhoids which prolapsed on

*Assistant instructor Tufts College Medical School, assistant surgeon Rectal Service, Outpatient Department Beth Israel Hospital.

withdrawal of the proctoscope, no other lesions were seen. Operation was advised, but was refused in favor of injection treatment. An injection of 1 cc of 5 per cent solution of sodium morrhuate was made under the mucosa above the internal hemorrhoid in the right lateral anterior quadrant, with care not to inject directly into the vein. The patient was asked to return in 1 week. No reaction except a sensation of fullness in the rectum was experienced. The patient returned in 2 weeks, and was again injected with 1 cc. of 5 per cent solution. Immediately after the injection she complained of nausea, pain in the lower abdomen, a desire to defecate, a feeling of weakness, and dyspnea. The face became pallid, the radial pulse was not felt, the pupils became dilated, and the blood pressure was 64/0. A subcutaneous injection of 1 cc. of a 1:1000 solution of adrenalin was given immediately, and a teaspoonful of spirits of ammonia in water was given by mouth. The attack lasted for 20 minutes, and the patient was allowed to leave the office after resting 1½ hours. She complained of feeling ill for 1 day. The drug was not used at subsequent visits.

DISCUSSION

It is well known that a drug idiosyncrasy may give symptoms identical with those observed in patients sensitive to pollens, foodstuffs or other material containing protein. The 2 cases just reported show that the severe anaphylactic reaction obtained by the use of sodium morrhuate can threaten the life of a patient. If this reaction is allergic, precautions identical with those taken against subcutaneous or intravenous medication with a foreign protein or protein-like substance must be observed in the use of sodium morrhuate as a sclerosing agent, whether for internal hemorrhoids or for any other condition. It might be well in each case to test for sensitivity to sodium morrhuate before using it. A patient may become hypersensitive to the drug if more than from seven

to ten days elapse between injections. In this event, immunization should be undertaken with small doses, beginning with 0.2 cc injected intradermally. To alleviate the extreme anaphylaxis in severe cases, 1 cc of adrenalin in 1:1000 solution should immediately be given subcutaneously. An ampule of coramine or atropin, gr 1/150 or 1/75 respectively, should be given hypodermically if there is cardiorespiratory embarrassment. In extreme cases artificial respiration should be resorted to.

SUMMARY

The use of a 5 per cent solution of sodium morrhuate for injections of internal hemorrhoids should be accompanied with the greatest of care in patients who have received previous injections with this solution, as well as in those receiving it for the first time.

Several theories have been advanced as to the causes of anaphylactic reactions from injections of sodium morrhuate.

Two cases of severe anaphylactic reaction are reported.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24121

PRESENTATION OF CASE

First admission A thirty-one-year-old, white, steam shovel operator entered the hospital with the complaint of headaches of ten days' duration.

Ten days before entry he fell on the stairs of a subway station, striking the back of his head. He felt a little dizzy and about an hour later suddenly felt nauseated and vomited. About two hours later he again vomited and developed a severe generalized headache. He was able to sleep that night and went to work the following morning. For the next six days he worked regularly but felt poorly, vomited frequently, and had severe, almost constant headache, neck pain, and low-back pain. Three days before entry he went to bed because of constant nausea. He was unable to eat anything, and the back pain became increasingly more severe. He noticed slight deafness in his left ear and had temperatures ranging from 100 to 101°F.

Twelve years before entry the patient slipped and struck the back of his head. He lost consciousness and remained unconscious in a hospital for seventeen days. The entire right side of his body was paralyzed, but he recovered completely and except for temporary deafness in the right ear remained free of symptoms until two years before entry when he was hit on the head and developed diplopia. Double vision had continued up to entry. His wife and four children were living and well. His past history and family history were otherwise noncontributory. He denied venereal disease.

Physical examination revealed a well-developed and nourished, slightly deaf man complaining of pain in the neck and back which was increased by moving. His heart, lungs and abdomen were negative. The neck was very stiff and painful on motion, and there was tenderness along the entire spine. Kernig's sign was positive and the reflexes were active and equal. There was weakness of the left external rectus muscle with diplopia to the left. The right pupil was larger than the left, but both reacted well to light and accommodation. There was slight weakness of the left side of the face, and hearing was poor in both ears. There was diminished sensation over the entire right side of the body, but vibration and position senses were normal. Motor activity was normal,

and there were no signs of cerebellar abnormality.

The temperature was 100.5°F, the pulse 47. The respirations were 26.

The urine examination was negative. The blood showed a red-cell count of 4,900,000 with 80 per cent hemoglobin and a white-cell count of 12,000 with 80 per cent polymorphonuclears. A blood Hinton test was negative. A lumbar puncture showed an initial pressure of 350 mm with normal pulse and respiratory oscillations. The spinal fluid was pink in color and contained 15,625 crenated red cells and 270 white cells per cubic millimeter, 78 per cent of the latter were polymorphonuclears. The Wassermann test was negative, the goldsol curve was 1333332100, and the sugar was 60 mg per cent.

X-rays of the skull and spine showed no evidence of fractures.

A second lumbar puncture two days after entry showed an initial pressure of 350 mm. The fluid was xanthochromic and contained 960 red cells. His condition improved slowly, and in two weeks he had only slight residual stiffness of his neck. At that time a lumbar puncture showed an initial pressure of 155 mm. The fluid was clear and colorless and contained no red cells, but did contain 25 lymphocytes. He was discharged on the twenty-first day.

Final admission (six months later) The patient remained perfectly well until the morning of entry when, while cranking an automobile, he suddenly developed severe pain in his head and neck. He went to work but felt sick and somewhat confused and therefore returned home later in the morning. He was given morphine, which afforded relief. Soon afterward, however, he became restless and vomited several times. The pain became more and more severe, and he finally lapsed into a semistupor.

Physical examination revealed a well-developed and nourished man in a semistuporous condition. His head was held back, his eyes were closed, and he was very restless. There was boardlike stiffness of the neck, and the Kernig sign was positive. The right pupil was larger than the left, and they reacted very slightly to light. There was blurring of the left optic disk. The reflexes were equal and active, but there were bilateral Babinski signs. The blood pressure was 110 systolic, 75 diastolic.

The temperature was 100.5°F, the pulse 80. The respirations were 27.

A lumbar puncture showed an initial pressure of 175, and the spinal fluid was grossly bloody. It contained 700,000 red cells and 500 white cells.

After a few hours he lapsed into a deep coma.

and began to have Cheyne-Stokes respirations. Two ventricular taps were done, both yielding grossly bloody fluid under a pressure of 360 mm. He died on the day of entry.

DIFFERENTIAL DIAGNOSIS

DR HENRY R VIETS. In summary this is a man of thirty-one who had three injuries to his head. At the age of nineteen he slipped and hit the back of his head, but he made a perfect recovery after a period of headache and vomiting. The second one was when he was twenty-nine, ten years later, and the third at thirty-one. A fourth and final cerebral episode resulted not from traumatic injury but from a strain six months later. It would seem as if we ought to connect all these episodes. The principal thing is that at each time he recovered practically entirely. He did have diplopia after the one at the age of twenty-nine which persisted, but from the first and third he made a complete recovery, which would suggest that we were not dealing with intracerebral disease but with intracranial disease on the surface of the brain. This and the evidence from spinal fluid examinations on the last two entries speak for subarachnoid hemorrhage. We make that diagnosis today more frequently than we ever did before. Blood in the spinal fluid in a young patient who recovers is practically always due to aneurysm. Occasionally we think of tumors, especially the blood tumors such as the angiomas. In spite of the fact that they are often on the surface they seldom bleed but give rise to Jacksonian epilepsy, which this patient did not have. The hemangioblastomas are practically always in the cerebellum and do not give rise to subarachnoid hemorrhage. We think, therefore, of aneurysm giving rise to four episodes of bleeding in this young man without very definite localizing signs. We shall have to say, knowing that aneurysms are usually in the circle of Willis and seldom elsewhere in the cranial vessels, that the aneurysm in this case was probably in the circle of Willis. I am not definitely able to say which part. The evidence for localization is not very good. He had a diplopia the last two years that may have been due to blood's penetrating the sixth nerve, but with its long intracranial course this sign does not help much in localization. He had weakness of the left side of the face. That would make us think of a lesion on the right side. On the other hand he had loss of sensation on the whole right side of the body, which would make us feel certain he had a lesion on the left side. He may have had two lesions, one on each side. It would seem that syphilis was not a factor. He is too young for arteriosclerosis, and it seems as though he had the usual congenital type of aneurysm which continued to bleed from time to

time giving this picture of chronic subarachnoid hemorrhage. The last and fatal one bled into the ventricles since the ventricular tap showed blood. He had bilateral Babinski signs and other more serious signs which are consistent with deep bleeding into the ventricle as well as the subarachnoid space.

DR TRACY B MALLORY. Dr Ayer, have you any comment?

DR JAMES B AYER. This man apparently had had attacks of bleeding nearly half his life. The one on the last entry happened when he was cranking his automobile. In other words something gave way on effort whereas the others were traumatic. I think the duration is enough to rule out most tumors. The hemangioma may run a long course but as Dr Viets said does not bleed spasmodically in this particular way. One would think of aneurysm or malformation of vessels rather than tumor. One questions whether some disturbance of vessels might occur from trauma which would subsequently bleed more easily. There might be a double lesion. Dr Kubik has spoken of a good many cases with double or multiple aneurysms.

There is one localizing sign in the first episode. He had double vision, and double vision is common, as Dr Albright first pointed out to us, in third-nerve palsy. It occurs in 50 per cent of the cases of aneurysm of the middle cerebral artery or at the junction of the cerebral and posterior communicating artery, which is the favorite place.

DR VIETS. The record says that there was weakness of the left external rectus muscle so it was sixth- and not third-nerve involvement. That is why I tried to point out that it did not help.

DR AYER. This also fits in with Dr Kubik's analysis of aneurysms to the effect that effort alone is often an explanation of bleeding. Several of our patients have had hemorrhage from the aneurysm on straining at stool.

DR MALLORY. By all odds the majority of vascular lesions that we find in patients with a history like this are arterial aneurysms in the neighborhood of the circle of Willis, but this case was not. It was a distinctly more unusual condition, which Dr Kubik will describe.

CLINICAL DIAGNOSIS

Subarachnoid hemorrhage, recurrent

DR VIETS'S DIAGNOSES

Subarachnoid hemorrhage, recurrent
Aneurysms, circle of Willis?

ANATOMIC DIAGNOSES

Hemorrhage, ventricular and subarachnoid
Aneurysmal varix

Bronchopneumonia
Pulmonary congestion and edema
Hydrohemothorax, bilateral

PATHOLOGICAL DISCUSSION

DR CHARLES S KUBIK Out of the cases of spontaneous subarachnoid hemorrhage which have come to postmortem examination in this hospital in the last seven or eight years, ruptured intracranial aneurysms accounted for 18, and I should say that not more than 6 or 7 were due to other causes, venous anomalies and hemangiomas of the choroid plexus being responsible for the majority. Considering the statistics and the similarity of the clinical manifestations produced by subarachnoid hemorrhage resulting from these various causes, ruptured aneurysm would be the logical diagnosis for anybody to make in this case. What we found was a saccular enlargement, 1.5 cm long and 0.7 cm in diameter, of a small vein lying against the inner surface of the left optic thalamus and entering the great vein of Galen with the left choroidal vein. Several very small, tortuous veins emptied into the sac. No connection with any of the arteries could be demonstrated.

DR MALLORY We do not ordinarily think of varicose veins as being of importance in cerebral lesions, but that seems to be essentially what we were dealing with here.

CASE 24122

PRESENTATION OF CASE

A forty-three-year-old Scotch laborer entered the hospital with the complaint of headaches of eighteen days' duration.

Eighteen days before entry while at work he noticed a sharp pain in the back of his neck and in the occipital region. He lay down for a while and then went home. The following day he went to see his doctor who prescribed Pluto Water. The next day he drove from Boston to New Brunswick on his vacation. His headache had continued intermittently and on the automobile trip was severe enough to prevent him from doing much of the driving. The headache continued during the subsequent two weeks and occasionally radiated to the frontal region. It was not sufficiently severe to keep him from having a fairly good holiday. Two days before entry his wife heard him make a very irrational statement which she knew to be wholly untrue. At the time of entry the patient was unable to give a clear-cut history. There were no data recorded relative to the mental changes during the two days prior to entry. All the information was given by his wife who was considered reliable.

His past history, so far as it could be obtained, was almost entirely negative. There had been a loss of 15 lb during the six months preceding his entry. He had no history of previous cerebral symptoms or of injuries of any importance. He had worn glasses for twenty years and had had them changed three months before entry. The diagnoses at that time were compound hyperopic astigmatism, hyperopia, and presbyopia. There was an indefinite history of a penile sore many years before entry. His wife had had one full-term child, which died twelve days after birth and three subsequent miscarriages. The family history was otherwise negative.

Physical examination revealed a well-developed and nourished middle-aged man. The heart, lungs and abdomen were negative, and the blood pressure was 140 systolic, 105 diastolic. He was somewhat disoriented and continually grasped the back of his head with his hands and grimaced as if in severe pain. He had no speech difficulty and yet was very slow in answering questions. There was no astereognosis. The Romberg sign was negative, and there was no nystagmus. Complicated movements were poorly performed, but the finger-to-nose and heel-to-knee tests were negative. The pupils were irregular, the right being larger than the left. The left pupil did not react directly to light, but did so consensually. The right reacted normally. The fundi were normal but the visual fields could not be determined. The cranial nerves were otherwise negative. Sensation was intact throughout, and motor activity was normal. The reflexes were active and bilaterally equal.

The temperature was 98.6°F, the pulse 75. The respirations were 18.

The urine examination was negative. The blood showed a red-cell count of 5,030,000 with a hemoglobin of 80, and a white-cell count of 12,500 with 73 per cent polymorphonuclears. The blood Hinton test was negative. A lumbar puncture showed an initial pressure of 210 mm with normal pulse and respiratory oscillations. The spinal fluid was clear and contained 6 lymphocytes per cubic millimeter, 47 mg per cent of protein, and 76 mg per cent of sugar. The goldsol curve was 0000000000, and the spinal fluid Wassermann was negative.

X-rays of the skull showed a calcified pineal gland displaced downward and backward. The pineal was not seen in the anteroposterior view.

His condition remained essentially unchanged for six days except that he became incontinent of urine and definitely drowsy. On the seventh day a ventriculogram was done. Dr Hampton's report reads as follows: 'The lateral ventricles are incompletely filled with air. There is no air in the third and fourth ventricles. The anterior and

inferior horns of the lateral ventricles are well demonstrated. The anterior horns are markedly displaced toward the left but they are approximately normal in size. There appears to be a filling defect in the body of the right lateral ventricle, and the body of the left lateral ventricle is incompletely filled at the same point. The inferior horn on the right is small and displaced downward whereas the inferior horn on the left is dilated and in normal position."

On the same day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR. ROBERT S. SCHWAB. In discussing the differential diagnosis I shall divide the symptoms and points in the history into three groups. First, those which I consider irrelevant, secondly, those which may be relevant, and thirdly, those I feel sure are relevant. The giving of Pluto Water, his wife's miscarriages, and the question of penile sore with negative Hinton and spinal fluid Wassermann I consider irrelevant. Now as to the second group—those that might be relevant—we have eye trouble. I presume he must have been to an oculist to get the eye diagnoses. He had lost 15 lb. in weight. He had a white count of 12,500 with 73 per cent polymorphonuclears. He also had slightly elevated spinal-fluid sugar and protein. As to third group I believe the following are definitely relevant: the left pupil fixed to light but with indirect consensual reflex to light, and the normal right eye, he also made an irrational remark, he could not perform complicated movements, he was stuporous and drowsy, the pineal was displaced downward and backward, the ventricular system was pushed to the left and there appeared to be a filling defect in the right ventricle, he also had pain in the back of the neck and head and incontinence of urine. As to location of the lesion, I do not believe it was frontal because the anterior horns were filled. It was not parietal because the reflexes were normal and there was no motor-system or pyramidal-tract involvement. He had no temporal lobe symptoms, such as astereognosis. We have no evidence of blindness (he did some driving on the way to Nova Scotia) so I presume it was not occipital. We have left, therefore, the region near the midline on the right side, as evidenced by the ventricles' being pushed to the left. It must be somewhat deep, and the regions which come under suspicion at this point are the corpus callosum, third ventricle, or the cortex above the corpus callosum and thalamus on the right.

He had an apparently fixed pupil when tested with direct light, but a good consensual reaction when the other eye was exposed to light. The

Argyll-Robertson pupil does not do that. It is fixed to both consensual and direct light. The only lesion that can cause a fixed left pupil with a normal light reflex from the right eye without other involvement of the sixth, fifth and third nerves would be a lesion in the right superior colliculus, that is near the posterior part of the corpus callosum, which is very close to the thalamus. In the differential diagnosis of this expanding lesion I should consider a tumor as most likely at this man's age. His symptoms were rapidly progressive, and a tumor in that region could easily result in such a clinical course. Secondly, I should think of cyst, and thirdly, abscess. Gumma and tuberculoma are fourth and fifth because of normal spinal fluid and negative Hinton and no evidence of tuberculosis elsewhere. To sum up, I should say he had a tumor in the region of the posterior part of the corpus callosum, either in it or above it, extending well to the right side of the midline.

DR. AUBREY O. HAMPTON. I cannot go farther than the report in the record. There seems to be a deep mass almost amputating the center of the body of the right lateral ventricle.

DR. TRACY B. MALLORY. The diagnosis that Dr. Schwab has made is approximately the same as that made on the ward.

DR. JAMES C. WHITE. My diagnosis was right-sided tumor, with the question of whether it involved the frontal or temporal lobe. His mental changes were more noticeable as you talked with him than one would realize from the history here. I believed it was rapidly growing because the symptoms were of such short duration, and the prognosis seemed to be very poor. I thought it was probably spongioblastoma multiforme.

DR. MALLORY. The operative findings were very much of a surprise. Perhaps Dr. White will tell us about them.

DR. WHITE. As soon as we had the bone flap turned down we could see bluish discoloration of the dura and it was obvious he had a hematoma. On opening the dura the hematoma appeared to cover the entire hemisphere and was a centimeter in thickness. There was a typical neomembrane surrounding the clot, and it was possible to dissect it out over the entire area.

DR. MALLORY. How often do you see a subdural hematoma in a case with no history of trauma?

DR. WHITE. We have seen several where we could not get a history. One patient I recall had bilateral subdural hematomas. He was an alcoholic and could give no accurate history.

DR. WILLIAM B. BREED. How is the patient now?

DR. WHITE. The patient died. It looked for a while as if he were going to recover consciousness. The afternoon after operation he was mumbling.

a little bit and making some movements, but next morning the coma was deeper. In spite of the ventricular shift we thought there might be a good-sized clot on the other side, as frequently happens, so I made a drill hole there but found nothing. The patient died four hours after that. In our experience patients who have had this degree of compression of the brain for a long period often die even though you remove the whole hematoma.

PREOPERATIVE DIAGNOSIS

Right frontal brain tumor

DR. SCHWAB'S DIAGNOSES

Brain tumor, right hemisphere over posterior part of corpus callosum?

Cyst in the same region?

ANATOMICAL DIAGNOSIS

Subdural hematoma, right

PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK: There was, so far as I can see, no good clue to the diagnosis. Since the specimen from this case reached us in fragmentary form after the surgical removal, let me demonstrate the lesion from another unoperated but essentially

similar case. The collection of blood, covering a large part of the lateral surface of the hemisphere, is enclosed between the dura on the outside and a thin, transparent, but fairly strong, fibrous membrane on the inside. The membrane arises entirely from the dura and is nowhere adherent to the underlying arachnoid. The hemorrhage, probably venous in origin, becomes surrounded by a membrane of newly formed connective tissue and, as the blood breaks down, the complex molecules likewise break down, the number of molecules increases and the material takes up fluid by osmosis. The encapsulated hematoma thus continues to increase in size and intracranial pressure rises. This is the brain from the case which was discussed and here are the remnants of the right-sided hematoma. There is flattening, though not very pronounced, of the convolutions of the left hemisphere and some displacement. Here, however, the third ventricle swings distinctly over to the left.

DR. SCHWAB: How do you explain the pupillary findings?

DR. KUBIK: I have no explanation for them.

A PHYSICIAN: Was there any evidence of vascular disease?

DR. KUBIK: No.

AN OPPORTUNITY FOR THE DISTRICT MEDICAL SOCIETY

THE Medical Society of the County of Westchester, New York, has adopted a periodic medical examination for adults in contact with children. This examination, which is performed at a special rate, includes particularly physical examination, a chest x-ray and a Wassermann test. After each semiannual examination, a medical card is issued to those who have no serious physical handicaps and have been found free from evidence of communicable disease.

Teachers, nurses and domestic servants naturally constitute the group toward which the efforts of the medical society are directed, and parents are urged to co-operate by insisting that these individuals who are in contact with their children hold medical health cards. In this way a class of

"health certified servants" may be created whose services will be more desirable and hence will draw better wages. Both employer and employee will benefit by such a co-operative scheme, far more desirable than any attempt at instituting compulsory examinations.

Legislation at best can go only a short distance in prescribing personal health measures, case finding in communicable disease has always been accomplished by the practicing physician or by voluntary co-operation on the part of the patient. Ill-health and uncleanly habits in servants are unmeasured but very potent sources of danger. The organization of health services patterned after that of the Medical Society of the County of Westchester might logically be recommended to our various district societies.

A YEAR OF HEALTH

THE health of the citizens of Massachusetts during 1937, according to the report of Commissioner Henry D. Chadwick, was distinctly above par. It will go on the record as a "healthy" year, with no epidemic of any dangerous communicable disease, and a decrease in the morbidity of most of the other reportable illnesses.

Of forty communicable diseases, about 98,000 cases occurred in 1937 as against 106,115 in 1936, a decrease of nearly 8 per cent. Diseases which, within a few years, were dread names to conjure with, are now of little moment. Typhoid fever, for instance, which ran as high as 3452 cases in 1910, occurred in barely over 100 cases in 1937. Diphtheria, with 10,322 recorded cases in 1917, showed less than 300 in 1937, and smallpox has not occurred within the State since 1932. The death rate from tuberculosis has halved within a generation, 1937 producing only about 5200 cases with 1730 deaths.

The virulence of the streptococcus of scarlet fever has decreased so markedly in recent years that it is now necessary to go to Russia or Roumania to study the disease in its old form, and in general a similar experience seems to have been encountered

with other forms of infection caused by hemolytic streptococci

Health runs in cycles with recurrent epidemic years of the various infectious diseases, but over a long period of time many of the infections have decreased in severity and methods of immunization have been developed for others of them. The expectancy of life has steadily lengthened as the infectious diseases have lost in virulence or have come under control, and more and more prominently the degenerative diseases of middle and later years stand out as our principal causes of death

CASE HISTORY No 64 PREMATURE SEPARATION OF THE PLACENTA

Mrs L. D., a seventeen-year-old primipara, was admitted to the hospital in convulsions when she was approximately thirty-eight weeks pregnant. Three weeks before entry she consulted a doctor for the first time, and he had examined the urine and pronounced it negative. There was some edema of the ankles at that time but no other signs or symptoms of toxemia. Edema of the face developed during the week preceding entry. The patient went to bed at 10 p. m., May 26, apparently in good health. She awoke at 1 a. m. complaining of pains in the abdomen and she vomited. At 3 a. m. there was a generalized convulsion lasting several minutes. The patient had four more convulsions before entry to the hospital at 5 a. m. and she never regained consciousness. During the seizures she voided involuntarily and frothed at the mouth.

The family history was negative for tuberculosis, cancer or nervous disease. Her mother died of blood poisoning following a miscarriage. Her father was living and well.

The patient had always been well. She had measles in childhood. There was no history of scarlet fever, septic sore throat, rheumatic fever, diphtheria or typhoid. The systems were negative. Her menstrual history was not elicited.

Physical examination revealed a well-developed, slightly obese young woman in coma and with stertorous breathing. The face was edematous, particularly about the eyes. The skin was dusky. The eyes were normal except for dilated pupils. The heart was not enlarged, the rate was regular, the sounds were of good quality, and there were no murmurs. Blood pressure was 228 systolic, 130 diastolic. The chest was symmetrical, expansion was equal and normal, and the lungs were clear. The abdomen was enlarged to the size of an eight and one-half months' pregnancy. Labor pains were noted about every five to seven minutes. The fetal heart was not audible. There was marked edema of the feet and ankles.

Soon after entry the patient was given gas-oxygen anesthesia and was catheterized. The urine boiled solid with albumin and there were many hyaline and granular casts. She was given morphine gr $\frac{1}{4}$ subcutaneously, and 20 cc of 10 per cent magnesium sulfate intravenously. She had one convulsion fifteen minutes after entry and another ten minutes later. Slight twitching of the face was noted three hours after admission. She was then given 15 cc. of magnesium sulfate intravenously and 360 cc of blood was removed by venesection. The systolic blood pressure fell to 170. The pulse was 72. At 9 a. m., four hours after entry, vaginal bleeding appeared, the uterus became spastic and there were no intervals of relaxation. The pulse rose to 140 within thirty minutes. A diagnosis of premature separation of a normally implanted placenta was made and immediate preparation was undertaken for delivery by cesarian section.

Under gas-oxygen anesthesia a low classical cesarian was performed without difficulty. The baby was stillborn. The placenta was separated over approximately one-half of its surface, and there was a moderately large retroplacental clot. There was no free blood in the uterine cavity. The uterine musculature was not abnormal in either appearance or texture. Bleeding was not excessive and was controlled by the intramuscular injection of 0.5 cc of posterior pituitary extract. The patient's pulse was very weak at the conclusion of the delivery but improved markedly following a transfusion of 600 cc of citrated blood.

The pulse dropped to 90 following delivery and the patient's general condition seemed improved. Suddenly she developed Cheyne-Stokes respiration and irregularity of the pupils. There was a short convulsion at 2:40 p. m., and she died at 2:48 p. m. At no time following the operation had vaginal bleeding been excessive and there had been no signs suggestive of internal hemorrhage. It was felt that death could largely be attributed to eclampsia, and that the premature separation of the normally implanted placenta was an incidental occurrence.

which added to the shock and jeopardized the patient's chances for recovery but was not actually the cause of death

Postmortem examination showed enlargement of the liver to 2220 gm. The organ was smooth and irregularly mottled with dark-red and light-yellow spots. The kidneys were grossly normal, as were the uterus and the brain. Microscopic examination revealed small subendocardial hemorrhages of the heart, numerous extensive periportal and interlobular hemorrhages of the liver with resulting degeneration and absence of liver cells, and swelling of the glomerular tufts of the kidney. The adrenal, cerebrum, cerebellum, pituitary and uterus were all normal. The findings were those of eclampsia.

Comment. The prognosis was very unfavorable when this patient entered the hospital. The subsequent separation of the placenta made the prognosis even graver. The prenatal care of course was most inadequate. Her one visit to a physician three weeks before delivery showed nothing abnormal except edema. Had she been seen routinely, this edema might well have shown that the patient had put on a great deal too much weight and might have made one suspicious of an impending toxemia. It is perfectly possible that there were no other symptoms at this visit except the edema. Eclampsia occasionally may be as fulminating as in this case. The separation of the placenta, in this instance definitely due to the toxemia, added the element of hemorrhage to the serious eclampsia. The more conservative method now in vogue of rupturing the membranes, packing the cervix, and applying a Spanish windlass certainly would not have added the degree of shock which the abdominal section undoubtedly did, but it probably would have made no difference in the ultimate outcome.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 28

BARNSTABLE

Sunday, April 3, at 4 00 p m., at the Cape Cod Hospital, Hyannis. Subject: Some Complications of Labor. Analgesics in Labor. Instructor: Christopher J. Duncan. John I. B. Vail, *Chairman*.

BERKSHIRE

Thursday, March 31, at 4 30 p m., at the House of Mercy Hospital, Pittsfield. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: Oliver H. Stansfield. Melvin H. Walker, Jr., *Chairman*.

BRISTOL SOUTH (Fall River Section)

Monday, March 28, at 4 30 p m., at the Union Hospital, Fall River. Subject: Bleeding in the Last Trimester of Pregnancy. Instructor: Meinolf V. Kappius. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*.

ESSEX NORTH

Friday, April 1, at 4 30 p m., at the Lawrence General Hospital, Lawrence. Subject: Bleeding in the Last Trimester of Pregnancy. Instructor: Judson A. Smith. John Parr, *Chairman*.

FRANKLIN

Wednesday, March 30, at 8 00 p m., at the Franklin County Hospital, Greenfield. Subject: Rheumatic Infection, Rheumatic Heart Disease. Instructor: Edward F. Bland. Halbert G. Stetson, *Chairman*.

HAMPDEN

Thursday, March 31, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject: Gonorrhea in the Male. Instructor: J. Dellinger Barney. George D. Henderson and George L. Schadt, *Chairmen*.

HAMPSHIRE

Wednesday, March 30, at 4 15 p m., in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject: The Use and Misuse of Prontylin. Instructor: Benjamin W. Carey, Jr. Warren P. Cordes, *Chairman*.

MIDDLESEX SOUTH

Wednesday, March 30, at 4 00 p m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject: Treatment of Burns. Instructor: Patrick J. Mahoney. Edmund H. Robbins, *Chairman*.

NORFOLK

Friday, April 1, at 8 30 p m., at the Norwood Hospital, Norwood. Subject: Drug Therapy in Pediatrics. Instructor: Warren R. Sisson. Hugo B. C. Ruemer, *Chairman*.

ESSEX NORTH DISTRICT MEDICAL SOCIETY

Attention of the members of the Essex North District Medical Society is called to the fact that the hour of assembly for postgraduate courses of the Massachusetts Medical Society being held in Lawrence this spring has been changed to 4 30 p m.

JOHN PARR, M.D., *Chairman*

DEATHS

ADAMS—DONALD STANSBURY ADAMS, M.D., of 27 West wood Drive, Worcester, died March 13. He was in his sixty-sixth year.

Born in Indianapolis, Indiana, he attended the schools in that city. He received his degree from the University of Virginia Department of Medicine in 1917 and interned at the University Hospital and the Boston City Hospital. During the war he served in the Medical Corps of the U. S. Army at Fort Devens. While there he met Dr. Homer Gage who persuaded him to go to Worcester, where he became resident surgeon at the Memorial Hos-

pital. He began private practice in 1923, but remained on the staff of the Memorial Hospital as assistant surgeon. He was, in addition, consulting surgeon at the Masonic Hospital, Shrewsbury, the Harrington Memorial Hospital, Southbridge, and the Webster District Hospital.

Dr Adams was a fellow of the American Medical Association and the Massachusetts Medical Society. Among his affiliations were memberships in the American College of Surgeons and the New England Surgical Society. He was a major in the Medical Reserve Corps.

His mother survives him.

CRANDELL—ARTHUR RICHMOND CRANDELL, M.D., died at his home, 48 Church Green, Taunton, March 19. He was in his sixty-ninth year.

A native of Taunton he attended the high school there, later graduated from Harvard University and received his degree from Harvard Medical School in 1896. Dr Crandell was a fellow of the American Medical Association and the Massachusetts Medical Society. His memberships included the New England Pediatric Society, the Taunton Doctors Club, the Harvard Clubs of Boston and Taunton, and the Old Colony Historical Society. Since 1900 he had been consulting physician at the Morton Hospital in Taunton.

His widow, a daughter, a sister and three grandchildren survive him.

NEW HAMPSHIRE MEDICAL SOCIETY

HISTORICAL NOTES

The New Hampshire Medical Society was incorporated by a legislative act signed on February 16, 1791. Dr Josiah Bartlett, president of the Senate, was one of the nineteen charter members who met at Exeter the following May for formal organization. Dr Bartlett, senior member of a family which has furnished five active officers and fellows to the society, was later president, and while governor of the State, refused a re-election. In his letter declining further honors he expressed the hope that the new society would "produce effects greatly beneficial to the community, by encouraging genius and learning in the medical science and discouraging ignorant and bold pretenders from practicing an art of which they had no knowledge." He set forth the aims of the society in the promotion "of better regulations than it had, and expressed the wish that "the practice of medicine in the State (upon which the lives and healths of our fellow citizens depend) might be under better regulation than in times past. John Rogers, of Plymouth, attended this meeting coming on horseback, a journey more laborious and time-consuming than would be necessary for a trip to the West Coast today.

David Ramsay, early pioneer physician, wrote one of the first and best histories of the Revolutionary War. It is still accepted as a classic.

The preceptor system prevailed in the State for many years. Medical schools then required that each attendant on a course of lectures be registered with a practitioner. It is reported that one popular physician in Portsmouth had twenty students at a time. When Dr Willard Parker left New Hampshire on his lecture tour from school to school, as he did for a considerable period each year, pupils followed him. Dr Frank Foster, of New York, in a short sketch of the career of Dr Charles Gage, of Concord, a leading surgeon for many years, states that Dr Gage always had many students, and that he himself studied with him for five years before venturing to attend a medical school.

It is interesting to note the frequency with which men, even in the very early days of New Hampshire, traveled and studied in foreign medical schools, both before and after graduation. Records show many instances of tremendous sacrifice involved in an absence from practice of many months, resembling the career of John Y. Bassett, of Huntsville, Alabama. The Alabama Student, immortalized by Osler in one of his finest essays.

Two New Hampshire members of the Continental Congress were Drs. Matthew Thornton and Josiah Bartlett, both signers of the Declaration of Independence. Bartlett was the first member to vote in favor of it, and at the signing of the document his name appears immediately after John Hancock, the president. "He had many times taken the responsibility for the birth of a man. Why should he shrink at the birth of a nation?" Dr Thornton and Dr Bartlett, like Benjamin Rush, of Pennsylvania, were young men, who showed the fiber of which they were made in their subsequent careers in medicine and in public service.

In its first century the New Hampshire Medical Society received seven hundred and twenty-four men into membership. The membership numbered two hundred and forty-five at the centennial exercises in 1891, and it was reported that honorary membership had been conferred on seventy physicians.

Conservative New Hampshire was slow in admitting women physicians to membership. By her association with the Manchester Medical Association, Dr Mary Danforth became a member of the Society in 1877. Dr Julia Wallace Russell, of Concord, in June, 1878, was voted the first woman member through action of the Council.

Following the vote of the Society in 1838 regarding the desirability of a national convention, the Medical Society of the State of New York recommended that the first meeting be held at Philadelphia in May, 1840. In 1839, at Smith's Tavern in Salisbury, Luke Howe, Thomas P. Hill and Thomas Chadbourne were chosen as delegates to the Philadelphia convention.

Dr William E. Maloney, of Keene, showed before the Cheshire County Medical Society in 1894 a patient on whom he had performed a cholecystectomy a few weeks before. This is undoubtedly the first removal of the gall bladder ever done in the State.

Adhesive plaster traction in the treatment of fracture of the femur originated with Josiah Crosby, of Manchester, who was of the family that gave many eminent medical men to this State. In 1849 an engineer, building a bridge over the Merrimack for the New Hampshire Central Railroad, suffered a fracture of the upper third of the bone. Dr Crosby applied, as was then customary, a long splint with a garter for extension and perineal band for counterextension. The patient bitterly complained of the pull of the garter about the ankle and instep. At his first removal from the bed the fragments parted, and the patient was informed that the apparatus must again be applied. Rebellion followed, and the doctor was urged to consider some less painful method of treatment. Long straps of adhesive plaster were applied to the sides of the leg, contact assured by snug bandages, and a weight attached. The fracture united and the patient lived many years. To distinguish Dr Crosby from a nephew of the same name he was ever after known as "Sticking Plaster Crosby." A writer in the *Philadelphia Medical Examiner* in 1852 attempted to claim priority for the discovery, but the writer's contentions were never accepted.

The income of physicians of the past is always of inter-

est to us moderns. A leading physician of our most wealthy city is reputed to have received no more than five thousand dollars per year in his most productive period, the late 1870s. He was paid seventy five cents per visit, a dollar and half for night visits, and a five-dollar obstetrical fee, one had to be industrious. A receipted bill of 1829 recently came to light with charges of "twenty cents for calling in and emetic and 'two dollars fifty cents for facilitating the birth of a child.' Yet not a few were able to leave modest competencies for their families.

At the meeting of the Society in 1894, Cyrus Kelley, in a paper "Then and Now," stated that the only instrument of diagnosis he owned in the early days of practice, aside from a crude clinical thermometer, was a stethoscope of cardboard, rolled into the shape of a cone, the base being applied to the chest and the apex to the ear. Laennec had just reported his observations on transmission of sound from the chest, but the wooden stethoscope had not then been offered. Even percussion came later.

Agitation for state licensure began as early as 1890, but the efforts of the organized profession were nullified by sectarian groups and reluctant legislators. The year 1897 marked the enactment of the first comprehensive statute for adequate protection of the public, and this statute has required very little amendment to the present. From July, 1897, when the law became operative, to 1938 over twenty-one hundred licenses have been granted. An average of about five hundred physicians have been in active practice each year.

At the 1895 session of the Society, following a discussion of the treatment of diphtheria, Dr. O. B. Douglas, of New York City, a prominent laryngologist, is quoted as saying "I do not believe that anti-toxine has come to stay. Professor Winters recently gave us [at the New York Academy of Medicine] an *expose* of its use at Wilford Parker Hospital. It seemed to do more harm than good."

Probably no other New Hampshire physician had, or ever can have, the unique distinction of Nathan Smith. A pupil of a prominent Vermont surgeon for a short time, he started a practice at Cornish, but two years later, realizing his incompetence, he registered at Harvard and received the degree of M.B. in 1790. He studied abroad returning six years later when he was honored by the degree of A.M. by Dartmouth College, and was elected to the Chair of Anatomy, Surgery, Chemistry, Materia Medica, and Theory and Practice in the medical school he was opening. In one room in Dartmouth Hall—laboratory, lecture room, library and dissecting room—he taught for four years. In 1811 Yale called him to New Haven to inaugurate the medical department. In 1821 he organized the medical school at Bowdoin College, giving all the lectures for two years, except those on chemistry and anatomy. Though he continued his lectures at Yale from 1813, he managed to hold a professorship in surgery and medicine at the University of Vermont. To him more than to any other man, it is believed, may be ascribed the advantages for medical education in America at this date [1891].

CANCER COMMITTEE

BIOPSIES

The most accurate method for the diagnosis of cancer is the microscopic examination of a portion of the tumor in the hands of an expert pathologist.

Details for performing biopsies vary with the individual situation, some are performed with the scalpel, others

with the electric knife, some by one or other of several punches which are on the market, and some by curet tage. *In any case a living and not a necrotic part must be removed, preferably with a bit of the surrounding tissue.* Merely clipping off of the surface of a tumor is not adequate.

The best fixative is 10 per cent formalin solution. The tissue should be immediately placed in a volume about ten times as great as the mass of tissue removed.

Biopsy is of value in following the course of treatment, —sometimes of critical value, —and *if properly done it is harmless.* Details of the history are of importance to the pathologist in all cases and should always be sent with the specimen. This is particularly important in those in which physiological activities are likely to be superimposed in and around tumors, such as menstrual hyperplasias in carcinoma of the uterus.

Occasionally a clinical diagnosis of cancer is not sustained by the microscopic picture, whereupon a *consultation with the pathologist is imperative.*

Biopsies are harmless if done properly, they usually settle the diagnosis, but pieces of tissues must be properly chosen for this purpose. They are also necessary in many cases to follow the course of treatment. The pathologist can be depended upon to use methods of preparation of his materials to ensure the quickest reports consistent with the accuracy demanded.

There is more danger from massage or repeated manipulation in making examinations, especially in cancer of the breast than in doing a biopsy.

HOWARD N. KINGSFORD, M.D.,
Committee on Control of Cancer

PNEUMONIA SERVICE

Dr. Travis Burroughs, secretary of the New Hampshire Board of Health, has issued detailed information regarding the pneumonia service. Complete instructions for typing sputum and for obtaining serum will be furnished on application. Arrangements have been made for designation of hospitals and laboratories for typing in various parts of the State, and, as rapidly as possible, more technicians will be trained for this work. The plans of the secretary include as complete a service as is offered by any other state. Only technicians with proper training and a high standard of performance will be offered the special course, so that a uniform and efficient service will be obtained, without waste of effort and money.

COMMONWEALTH FUND FELLOWSHIPS

Announcement is made by the Committee on Medical Education and Hospitals that Commonwealth Fund fellowships are available, for members of the Society, in medicine, pediatrics, obstetrics and office surgery. Fellows must be graduates of Class "A" medical schools, residents of communities of less than ten thousand population and must have been in practice at least five years. A generous stipend is allowed for expenses, and tuition is paid by the Fund. Application blanks may be obtained from P. O. Box 48, Hanover, N. H. Dr. Samuel T. Ladd, president of the Society, has endorsed this plan, and urges eligible physicians to make application.

SOCIETY NEWS

Dr. Sven Gundersen, of Hanover, read a paper on "Serum Treatment of Pneumonia" at a meeting of the Carroll County Medical Society at Conway on February 20.

Dr. Edna Walck, the first woman member to be honored with the presidency of the Dover Medical Society,

was in the chair for the regular meeting on March 2, when Dr. George Cumming, of Portland, gave a clinical talk on "Nose and Sinuses." This society is one of the oldest city associations in the country with continuous existence, having been organized in 1849.

Frank Sulloway, Esq., legal adviser of the Society, was the speaker at the February meeting of the Dover Medical Society. His subject was "Medical Liability."

BIRTH

On February 27, to Dr. and Mrs. Samuel J. King, of Farmington, a son, Robert Bruce.

PERSONALS

Dr. Roscoe Blanchard, of Dover, has recovered from a recent illness and has resumed his practice.

Dr. Peter F. Doyle has been elected city physician of Dover for the term 1938-39.

Dr. Nathan Milliken, of Hanover, has been elected an associate of the American College of Physicians.

Dr. Ralph Miller, of Dartmouth Medical School, was a delegate to the recent meeting of the Council on Medical Education and Hospitals at Chicago.

Dr. Montfort Haslam, formerly resident physician at St. Paul's School, Concord, opened an office at 18 Church Street, Littleton, on March 1. Dr. Haslam has been for the past year in New York City, where he has taken postgraduate work at the Post-Graduate Hospital, Willard Parker Hospital and Margaret Hague Maternity Hospital.

Dr. George S. Foster, Manchester, is the donor of the Mt. Washington Marathon Trophy now on display at the New Hampshire Historical Society. The large silver cup already bears the names of two winners who have made the ascent of the mountain in less than one hour and twenty minutes.

NOTES

Representative Charles P. Tobey has introduced a bill in the House of Representatives carrying an appropriation for the establishment of a veterans' administration general hospital in the southern part of New Hampshire.

Announcement has been made by the Manchester Council of Social Agencies concerning the recent formation in that city of a permanent social hygiene committee, with Dr. Harry W. N. Bennett as chairman. This committee is to be expanded to include both professional and lay people and will confine its activities mostly to maintaining a speakers' bureau and literature in the field of social hygiene.

Dr. Ralph Jones gave an address on "The Influence of Medicine on History" for the Whitefield Rotary Club on February 19.

The trustees of the Wentworth Hospital, Dover, announce the appointment of Miss M. A. Hall as superintendent, and the reorganization of the nursing and administrative staff.

Dr. Robert B. Kerr, executive secretary of the New Hampshire Tuberculosis Association, announced in his annual report that there are 6223 active arrested and contact cases of pulmonary tuberculosis in the State. New Hampshire with a death rate of 33.7 per 100,000 has the lowest rate in New England, and is eighth lowest in the continental United States. Since the association was organized, deaths per year have decreased from 500 to 172.

Dr. Warren Phillips, of Boston, was the speaker at a meeting of the Wolfeboro Rotary Club on February 15. His subject was "What the Layman Should Know of Syphilis." The Tufts College Medical School talking film "The Training of the Doctor" was shown.

Under the direction of Mrs. Harry W. Smith, of Durham, the annual drive for enrollment in the Women's Field Army will be held during the month of April. The State has been divided into districts roughly corresponding to the location of the clinics of the State Cancer Commission. Physician and nurse speakers will address groups of both men and women.

The income of a trust, created by the will of Volna K. Kelton, of Grafton Center, is used for the payment of a bonus to the local physician. Dr. Walter D. Berry has been retained to provide medical service for a group of towns among which are Grafton, Danbury, Orange, and Springfield.

DEATHS

LEETE—GEORGE E. LEETE, M.D., who had practiced medicine in Concord for the past forty-four years, died at his home, Tuesday, February 22. He was in his eighty-seventh year.

Dr. Leete was born in Claremont, New Hampshire, March 29, 1851, the son of George H. and Sarah F. (Chase) Leete, his ancestors were among the first to settle in Connecticut and later moved to New Hampshire.

He graduated from the Dartmouth Medical School in 1878, after which he established a practice in Canaan where he remained for seventeen years.

In Canaan, Dr. Leete was a member of the School Board in 1893 and of the Board of Health in 1894. The remainder of his life was spent in Concord. The New Hampshire Medical Society gave him its gold medal for fifty years of medical practice in 1934.

On February 14, 1878, he married Katherine S. Sawyer, now deceased. One son, Dr. Edward Don Leete, of Boston, survives him. A second son, George Paul Leete, died.

Dr. Leete was a member of the New Hampshire Medical Society and the American Medical Association. He was also an honorary member of the Jefferson College Alumni Association at Philadelphia.

LOBDELL—ALBAN J. LOBDELL, M.D., died March 5 in Keene after a short illness. Dr. Lobdell had been one of Winchester's most prominent residents since opening his office in 1893. He was interested in community affairs and had served as president of the Board of Trustees of the Winchester Library and as a member of the Board of Health for several years.

Dr. Lobdell was born in East Berne, New York, April 2, 1868, a son of Adoniran J. and Eleanor (Veeder) Lobdell. He started teaching school when eighteen years old and at the same time was studying medicine. He graduated from the New York Homeopathic Medical College in 1893.

He was a member of the New Hampshire Medical Society, the Cheshire County Medical Society and the American Institute of Homeopathy.

On November 25, 1896, he married Miss M. Grace Ball, of Winchester, who survives him. He is also survived by two sons, Alban J. Lobdell, Jr., of Woburn, Massachusetts, and Winston B. Lobdell of Stoneham, Massachusetts, a brother, Rev. Isaac Lobdell, pastor of the Universalist Church in Attleboro, Massachusetts, and two grandchildren.

MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES
IN MASSACHUSETTS FOR FEBRUARY, 1938

DISEASES	FEBRUARY 1938	FEBRUARY 1937	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	0	1
Chickenpox	1608	1438	1225
Diphtheria	11	17	41
Dog bite	525	572	451
German measles	80	77	503
Gonorrhea	445	429	406
Lobar pneumonia	519	964	651
Measles	811	3502	3539
Meningococcus meningitis	9	15	9
Mumps	777	735	889
Paratyphoid B	1	2	0
Scarlet fever	1213	1002	1058
Syphilis	461	509	401
Tuberculosis pulmonary	195	252	235
Tuberculosis other forms	23	21	30
Typhoid fever	5	3	5
Undulant fever	3	1	2
Whooping cough	454	1831	993

*Based on figures for preceding five years

RARE DISEASES

Diphtheria was reported from Boston, 2, Fall River, 2, New Bedford, 1, Swampscott, 1, Taunton, 5, total, 11

Dysentery, bacillary, was reported from Boston, 2, Brookline, 1, Greenfield, 1, Peabody, 1, Worcester, 1, total, 6

Meningococcus meningitis was reported from Boston, 2, Cambridge, 1, Chicopee, 1, Holyoke, 1, Tewksbury, 1, Waltham, 1, Westfield, 1, Worcester, 1, total, 9

Paratyphoid B was reported from Belmont, 1

Pfeiffer bacillus meningitis was reported from Attleboro, 1

Septic sore throat was reported from Beverly, 2, Boston, 5, Brookline, 1, Cambridge, 1, Chicopee, 1, Lawrence, 1, Medford, 1, Melrose, 1, Northfield, 5, Quincy, 1, Springfield, 1, Winthrop, 1, total, 21

Trichinosis was reported from Boston, 3, Springfield, 1, total, 4

Typhoid fever was reported from Boston, 1, Chelmsford, 1, Haverhill, 1, Quincy, 1, Westfield, 1, total, 5

Undulant fever was reported from Chicopee, 1, Natick, 1, Pittsfield, 1, total, 3

The incidence of diphtheria showed record low figures for the second consecutive month.

German measles, mumps and tuberculosis (other forms) were reported below the five year average.

Chickenpox for the second consecutive month showed record high incidence.

The incidences of scarlet fever and undulant fever were above the five year average.

The incidences of meningococcus meningitis and typhoid fever were not remarkable.

Lobar pneumonia, whooping cough, measles and pulmonary tuberculosis were reported at figures considerably below the five year average

The reported cases of animal rabies gave evidence of wide distribution throughout the State. New foci were reported in Boxford, Chelsea and Sutton. Previously noted foci in the North Metropolitan area and in Wilmington were active

TUBERCULOSIS ABSTRACTS

THE EFFECT OF CONTAGIOUS DISEASES ON TUBERCULOSIS

An attack of acute contagious disease in a child infected with the tubercle bacillus is something nearly every physi-

cian dreads. It has long been taught that measles, whooping cough and influenza predispose to tuberculosis and aggravate existing clinical tuberculosis. It is also commonly said that the acute contagious diseases, particularly measles, depress or obliterate the child's capacity to react to tuberculin. These opinions, seldom supported by convincing facts, have recently been challenged. J P Nalbant in a paper entitled "The Effect of Contagious Diseases on Pulmonary Tuberculosis and on the Tuberculin Reaction in Children" (*Am Rev Tuberc* 36 773-777, 1937), reports on a study made of 118 children convalescing from tuberculosis who developed acute contagious diseases while in the sanatorium. Excerpts from his paper follow

Several writers state that during an attack of measles the tuberculin test becomes negative. Some assert that intercurrent infections, particularly measles, stimulate activity in many cases of tuberculosis. In one series of 37 cases of tuberculous children who developed measles, the tuberculin test done by the Pirquet method showed that the reaction became negative in all at the appearance of the eruption, but became positive again in half of them by the seventh day. Other writers express different views. Chadwick, for example, found that a group of tuberculous children who reacted positively to tuberculin showed no change roentgenologically and no change in their tuberculin reactions during and after measles. Berghoff studied 596 cases of measles in the army and found only 1 case of frank active tuberculosis following directly after a measles infection.

Scattered studies made in Europe to determine the effect of whooping cough, chickenpox, scarlet fever and measles on the tuberculin reaction, and on active or inactive tuberculous lesions, indicate that the effect of the contagious diseases on tuberculosis has been exaggerated and may be very doubtful. This supports the findings of the author in a study made at the William H. Maybury Sanatorium, which included 43 children with measles, 39 with chickenpox, 16 with whooping cough, 13 with scarlet fever, 30 with mumps and 6 with diphtheria, making a total of 147 cases of acute infectious disease in a group of 118 children convalescing from pulmonary tuberculosis of the childhood type. The ages of the children ranged from six months to fifteen years. All had x ray examinations of the chest a short time before the onset of the contagious disease and directly after the expiration of the quarantine period. Eighty three of the 118 children had active pulmonary tuberculosis of the childhood type, the remaining 35 had quiescent or apparently arrested disease.

In 4 of the 43 cases of measles the intracutaneous tuberculin test with old tuberculin became negative to a dose to which they were positive before, but was again positive two weeks after the disappearance of the eruption. Six cases showed, by roentgenological examination, an increase in the pre-existing tuberculous process but none of these occurred in less than one month after the measles. In each instance the exacerbation of the tuberculosis was an evanescent occurrence and all recovered completely in a few months.

Two of the 16 children with whooping cough showed exacerbation of the tuberculous disease. In 1 case this occurred during the course of whooping cough but subsided promptly. Three of the cases of chickenpox experienced extensions of their tuberculous lesions none of them showed any change in the tuberculin reaction. Of the 25 children with mumps, 24 were positive to tuberculin before and after the disease. However, a change in the type of the reaction was noticed in several. None of the

mumps patients showed reactivation or exacerbation of their tuberculosis

Of the 13 cases with scarlet fever, only 1 showed a spread of the tuberculous process. None of the 6 cases of diphtheria experienced any ill effects so far as their tuberculosis was concerned. The children with scarlet fever and diphtheria were not tested with tuberculin.

In the discussion, the author points out that only 12 children of the 118 showed any increase in the tuberculous lesions during convalescence. This closely parallels the experience of similar groups of patients whose tuberculosis was not complicated by acute contagious diseases. In the great majority of those who showed increase in tuberculosis, the extension occurred several weeks after the intercurrent disease had subsided. None of these remissions occurred in quiescent or apparently arrested lesions showing that the old foci were not disturbed by the intercurrent contagious disease. The remissions seen in the active tuberculous lesions could be safely considered coincidental and unrelated to the contagious disease.

Very little evidence was found to support the contention that measles or any of the other contagious infections have a depressing effect on the body's capacity to react to tuberculin. In the majority of previous studies the Pirquet method was employed for giving the tuberculin test. This may explain the apparent discrepancy, because the Mantoux test, which is more precise, was used in all of the author's cases.

RESULTS OF TUBERCULIN TESTS

Tuberculin reaction studies made with purified protein derivative in various parts of the country were collated by the Statistical Service of the National Tuberculosis Association. The graph, based on 56,638 tests, pictures the

steady increase in the percentage of reactors with increasing age. It contrasts also the far greater percentage of reactors among contacts as compared with those among non-contacts.—*Tuberculosis Abstracts* March, 1938

CORRESPONDENCE

FELLOWSHIP IN DIABETIC LABORATORY WORK

To the Editor A fellowship in diabetic laboratory work for technicians working in other hospitals or in doctors' offices has been created at the New England Deaconess Hospital for the remainder of this year or perhaps longer if it meets a need. Often a graduate technician may require simply a few days instruction, rarely over one or two weeks.

It has been reported to me that our visiting doctors are often interested particularly in rapid methods for quantitating sugar in the urine, in capillary blood sugar tests for children and in various measures by which costs are reduced.

The technician will be expected to secure rooming accommodations, but meals will be provided by the hospital and there will be no charge for instruction

Should a technician care to apply for this fellowship, the application should be accompanied by a letter, addressed to me, from the superintendent of the hospital or doctor by whom he or she is employed.

WARREN F COOK, *Superintendent.*

New England Deaconess Hospital,
Deaconess Road,
Boston, Massachusetts.

INTERCITY HEALTH-CONSERVATION CONTEST

To the Editor To the medical profession of Boston, the Boston Health Department expresses its gratitude for the co-operation received from the doctors who gave so generously of their time to compile and place at the disposal of the department data upon immunizations and other public health measures performed by them for their private patients during the year 1937

This material was used in the recently completed Intercity Health-Conservation Contest. These contests, sponsored by the United States Chamber of Commerce and the American Public Health Association, have been going on for a number of years. This is, however, the first time that Boston has entered the contest, and the decision to do so was arrived at upon rather short notice and late in the day. Hence, the sudden call upon individual doctors and organized agencies for the necessary data.

The response from private physicians to our request was most gratifying, both as to the number of doctors taking the trouble to answer the appeal and also the volume of what may be classified as public health or preventive functions, privately performed. For instance, 3328 Boston children were immunized against diphtheria, 6390 children were vaccinated against smallpox, 3000 infants and 1800 preschool children were periodically examined for the purpose of keeping the children well and over 19,000 prenatal visits were made in the private practices of about 25 per cent of the members of the Massachusetts Medical Society with offices in Boston.

This department also thanks all official and voluntary agencies engaged in public health work which contributed information upon numbers and kinds of public health functions performed by these agencies during the year 1937, as well as the Committee of Citizens acting for the local Chamber of Commerce, whose members aided in the fact findings necessary for the required purposes of the contest.

H. F. R. WATTS, M.D.,
Health Commissioner

City Hall Annex,
Boston, Massachusetts.

REPORTS OF MEETINGS

NEW ENGLAND HEART ASSOCIATION

The regular monthly meeting of the New England Heart Association was held at the Boston City Hospital on December 13, 1937. The following program was presented

TWO UNUSUAL CASES OF DISSECTING ANEURYSM OF THE AORTA. Soma Weiss, M.D.

Two cases of dissecting aneurysm of the aorta were presented, demonstrating (a) dissection causing compression of the coronary artery and cardiac infarction and (b)

simultaneous presence of syphilis and dissecting aneurysm. Both are reported in detail in this issue of the *Journal*

THE CARDIOVASCULAR EFFECTS OF INTRAVENOUS INJECTIONS OF FIFTY PER CENT DEXTROSE AND SUCROSE IN NORMAL PERSONS AND IN PATIENTS WITH HEART FAILURE
Laurence B Ellis, M.D

An investigation was made of the effect on the circulation of the intravenous injection of 100 cc. of 50 per cent glucose or sucrose solutions. Studies were made on 27 subjects. These fall into three general groups. The first comprises 6 subjects with normal cardiovascular systems. The second consists of 10 cardiac patients without edema, including 2 who had recently had severe coronary occlusions, 2 who had never experienced heart failure, 3 who had recently recovered from congestive failure and 3 who were in definite failure without peripheral edema. The third group of 11 cardiac patients all had severe congestive failure with edema which varied in degree from moderate to massive. The cardiovascular effects of the intravenous injection of dextrose or sucrose solutions are similar. There was no significant change in the arterial blood pressure or in the heart rate. The venous pressure tended to rise during the course of the injection, and this increase was as much as 7 cm of water. In most instances it fell progressively after the injection had stopped. The plasma volume was increased at the end of a half hour on an average of 9 to 12 per cent, or about 300 cc., and in some instances by as much as 20 per cent, or 600 cc. This increase in plasma volume is due to the drawing of fluid from the tissue spaces to the blood stream by the hypertonic action of the sugar introduced. The dilution of the plasma was temporary and had usually disappeared at the end of one hour. No significant differences in the response of the circulation could be detected which depended on the degrees of heart failure.

FRIEDLANDER'S BACILLUS PERICARDITIS. James M. Faulkner, M.D

A man of forty-nine, who was a heroin addict and an alcoholic, entered the hospital with a history characteristic of the onset of pneumonia three days before. On admission, he presented signs of consolidation at the base of the right lung, fever, prostration and leukocytosis. The sputum contained many large, gram negative rods, and on culture Friedländer's bacilli were the predominant organisms. The same bacterium was recovered from the blood culture on the day of admission, and subsequently from pleural exudate on both sides. For four weeks there was gradual clinical improvement with subsidence of fever and leukocytosis. The pulse rate remained elevated, however, and the electrocardiogram showed pronounced changes in the T wave. Orthopnea, increased venous pressure, enlargement of the liver, and general anasarca developed. Finally, rales appeared in the lungs and he died suddenly sixty days after admission.

Postmortem examination revealed, in addition to areas of bronchopneumonia with marked fibroblastic proliferation in the lung and pleura, a very much thickened and adherent pericardium, which cut with difficulty. There was 300 cc. of purulent exudate in the pericardial cavity. Microscopically, the pericardium consisted of fibroblasts diffusely infiltrated with lymphocytes and macrophages. The histologic appearance of the pericardium was consistent with a lesion of less than nine weeks duration.

The case illustrates an unusual form of acute pericarditis which went on to the obstructive form of adherent pericardium in a relatively short period of time.

THE MYOCARDIUM IN FATAL CASES OF HEMOLYTIC STREPTOCOCCUS INFECTIONS. G. Kenneth Mallory, M.D., and Chester S. Keefer, M.D.

The sections of myocardium from cases dying from scarlet fever, erysipelas, streptococcus sore throat and surgical *Streptococcus hemolyticus* sepsis were studied, and the changes found were illustrated by lantern slides. These changes consisted of focal accumulations of lymphocytes, plasma cells and histiocytes beneath the endocardium, in the perivascular areas and between the muscle fibers. In several more acute cases, organisms (cocci) without reaction or organisms with an acute reaction of polymorphonuclear leukocytes were found. These lesions had the same distribution as those already described. Similar reactions, both acute and chronic, were found in other organs, particularly the kidney, liver, pancreas and adrenal.

These changes were found in 61 per cent of the hearts examined. The lesions were similar and equally common in all age groups. They were commonest and most marked in patients dying from six to ten days after the onset of the infection, but were found as late as the thirtieth day. The majority of the cases had a positive blood culture for *Streptococcus hemolyticus* at the time of autopsy.

In conclusion, it was stated that the lesions described may be infectious in origin and the result of the reaction of the tissues to the presence of invading organisms and not, as other workers have suggested, a reaction to a circulating bacterial toxin. It was felt, however, that the degree of this reaction may be somewhat enhanced as a result of antigen antibody response.

INFARCTION OF THE HEART. A MORPHOLOGICAL AND CLINICAL APPRAISAL OF 300 CASES. William B. Bean, M.D. (presented by Paul Kunkel, M.D.)

A detailed study of 300 autopsied cases of cardiac infarction at the Boston City Hospital was made. The material was discussed under three titles: (1) predisposing and precipitating conditions, (2) clinical and morphological observations, (3) clinical course and morphological findings.

All possible correlations of the assembled data on these cases were made. These included distribution by decades, which showed that initial infarction in both men and women was highest in the seventh decade. Initial infarction in hypertensives was higher in the sixth and seventh decades, as compared with the whole group, as was also the case in those with family history of vascular disease. There was a low incidence of initial attacks and deaths during the summer months. A study of the occurrence of various types of arteriosclerosis showed that the overwhelming majority of cases presented coronary artery disease, and that 20 per cent of the infarcts followed arterial narrowing without thrombosis. The importance of surgical and medical shock was stressed as an occasional precipitating factor. A third of all cases presented pre-existing cardiac failure, and in this series dyspnea and edema did not protect from anginal pain. Alcohol and tobacco seemed to play an unimportant role, excepting perhaps alcoholic coma. Other correlations included coexisting diseased states, of which diabetes mellitus and gallbladder disease were conspicuous. An analysis of circumstances at onset of infarction indicated that time of day, occupation and activity were unimportant factors. The majority of patients died of congestive failure.

THE EFFECT OF EPINEPHRIN AND PITRESSIN IN SODIUM-NITRITE COLLAPSE. Eugene A. Stead, Jr., M.D., and Paul Kunkel, M.D.

Epinephrin and Pitressin are drugs which are frequently used in the treatment of collapse and shock. Since controlled observations are difficult to make in patients who are critically ill, it was necessary to find a type of collapse which would reproduce the circulatory changes observed in clinical shock and which could be produced at will. Sodium nitrite in the upright position produces the manifestations of collapse ending in syncope by increasing the venous distensibility with resulting pooling of the blood in the lower part of the body. The arterioles are constricted but tissue anoxia results as the venous return to the heart decreases. (See Wilkins, R. W., Weiss, S., and Haynes, F. W. *J. Clin. Investigation* 17: 41-51, 1938.)

Epinephrin and Pitressin are not effective in preventing sodium nitrite collapse. In fact, they tend to precipitate it. They do not cause enough constriction of the venules to overcome the pooling of blood in the dependent portions of the body, but do produce marked arteriolar constriction and a decrease in blood flow as measured in the hands. This increases tissue anoxia and heightens the collapse. The fact that with epinephrin and nitrite the symptoms of collapse often occur with the blood pressure at higher levels than with nitrite alone indicates that the level of arterial pressure is not a sure guide to the condition of the patient.

REPAIR IN CORONARY SCLEROSIS. Timothy Leary, M.D.

From a study of 200 advanced lesions in 120 cases of coronary disease it became evident that every advanced atherosclerotic lesion is vascularized. On the contrary, the early lesions are not vascularized. Nutrition of the normal intima is by diffusion of material from the blood in the lumen. This diffusion is adequate to care for the nutrition of early atherosclerotic lesions as well. When a lesion enlarges to the point at which diffusion nutrition ceases to be adequate, necrosis occurs. If the lesion is to enlarge beyond this point, a new source of nutrition, that is, by vascularization, is necessary. Vascularization in young individuals frequently arises directly from the lumen, in the form of a capillary circulation which does not tend to differentiate further. The persistence of this central, capillary circulation well into the middle period of life in many cases suggests that it may lengthen life, perhaps by ensuring nutrition to the portion of the lesion most exposed to injury that may result in thrombosis. In older persons vascularization arises from the vasa vasorum, and differentiation into arteries and veins usually occurs as the lesions age. Hemorrhage in coronary lesions originates from these new vessels, and is usually terminal. Since it arises from vessels which are produced in the repair of well-established and enlarging, atherosclerotic lesions, hemorrhage cannot be the source or cause of atherosclerosis. Repair of thrombosed vessels by canalization may in rare cases re-establish in considerable degree the crippled, local circulation.

THE CONGRESS ON MEDICAL EDUCATION

The Thirty Fourth Annual Congress on Medical Education and Licensure was held in Chicago on February 14 and 15 of this year and while little new was presented, there was renewed emphasis on one of the principles of medicine which was dwelt on last year, namely, that the quality of the person who renders medical service is of prime importance. From time to time the emphasis has shifted premedical education, the medical curriculum,

the faculty, the mechanics of education as it concerns plant and equipment, whether in the school itself or in the hospital, and finally the person to be educated.

The opening address was by the chairman of the Council on Medical Education and Hospitals, Dr. Ray L. Wilbur, of Stanford University, who began with a reference to the recently completed study of medical schools in the United States, the results of which have not yet been made public. Many deficiencies have been found, but it has been thought wise to refrain from giving publicity to the parts of the report showing such deficiencies before the schools themselves have been given opportunity to make good. In general the schools have shown great willingness to follow the recommendations of the Council. Uniformity in method or procedure or curriculum has not been sought, but an effort has been made to set forth a reasonable minimum for each school, taking into consideration all the resources of the school, and most important of all, what may be expected of every physician who holds himself out as qualified to treat the sick. Both tangibles and intangibles must be considered. It is elementary that perhaps the most important fact in determining what comes out of a medical school is what goes in. If only poor material goes in, the school is doomed to failure.

The Council has made certain recommendations. The first is that the minimum requirement of two years of college work be raised to three. The percentage of graduates of medical schools who have actually had three years of premedical work has been steadily rising in recent years and is now over 90.

The reasons given for this recommendation are several. In the first place, although the mere length of time spent in college is not a good test of fitness, the additional time may be used to give a more nearly adequate testing of the material. We are too often deceived, or deceive ourselves, by formal standards. There is the oft repeated statement that each year about 12,000 candidates try to squeeze themselves into 7000 places in the entering classes in medical schools, and that of the rejected 5000 many would be accepted if the schools were larger. But a more intensive study of the real qualifications of those accepted suggests that perhaps not more than 4500 are really well qualified to undertake the study of medicine.

Modern scientific medicine requires for its understanding more knowledge of the fundamental sciences on which it is built, and more of the sciences allied to the basis of professional activities. Employing two words in a narrow and popular and therefore inaccurate and perhaps misleading sense, the physician needs science and culture in his education. Science of course may be cultural, but what the physician needs is an understanding of the human body as a very complex machine and an understanding of the human being as an infinitely complex personality. Two years in a special premedical course, whether in junior college or in some other type of institution, do not ordinarily give a sufficiently wide and deep foundation for the heavy superstructure of purely professional education. There are those who think that four years in college are not too much, but the wisdom of adopting this as a minimum requirement for all is questioned.

As something over 95 per cent of all graduates of medical schools now take an internship before entering practice there has been a tendency to make such apprenticeship a formal requirement. One finds confusing tendencies, as the payment in some institutions of substantial salaries to interns. One should keep in mind the various purposes of the internship and should emphasize that which in the

long run will give the best result. The ideal is the education of the intern. That the ideal cannot be pursued uncompromisingly is evident at once, because every hospital of 100 beds certainly needs the services of the intern, but a hospital is not primarily an educational institution for any group. Such education, whether of medical student, intern, nurse, teacher or administrator, is a secondary function which many hospitals may never be able to perform in a satisfactory manner. It is, however, well established that patients in a hospital will receive better care, if, other things being equal, the hospital participates in some form of education. If interns are paid a substantial salary, the hospital is likely to think that its obligation closes with the sending of the pay check, and deterioration of the medical education of the intern is sure to follow.

One of the crying needs is an authoritative determination of when a "specialist" is not a specialist. "Self-anointed" specialists are all too common. It may be that governmental regulation will be the best method of control, but the voluntary specialist examining boards, of which there are now twelve, have begun a noteworthy and valuable service. Already their influence has been important in clarifying some of the issues involved in graduate medical education but their work lies chiefly ahead of them. They are confronted by at least one danger, that of regarding themselves, as did the medical guilds, as formed for the purpose of protecting themselves.

If one surveys the whole field of the healing art, the widespread interest in it on the part of the public, and the vast complexity of its problems as an integral part of the life of society, one comes to the very simple conclusion that what medicine needs most, in order that the profession may meet its responsibilities, is character and brains and leadership. It is the part of medical education to discover, select and train, in such ways as may be possible, physicians who not only minister to the needs of individuals but also are able to take their proper place as advisers and participators in shaping the policies of the communities, whether small or large, of which they are a part.

It is not likely that the problems of professional licensure will be easily solved in the best way by the efforts of one profession alone, and the general problems of this nature were discussed by Mr. John K. Clark, of the New York Board of Law Examiners. In spite of the many differences of background of lawyer and physician, one of which is that the lawyer practices as an officer of the court and therefore under the judiciary while the physician is licensed under legislative authority, certain common principles of qualification exist, such as knowledge of the principles of the subject, ability to analyze a complicated state of affairs and to select the principles which apply to the specific problems involved, skill in the application of these principles, and ability to make a clear statement of the application. But the determination of fitness, the prime function of a licensing board, has its chief difficulty not in the field of acquisition of knowledge by the candidate but in the field of character. Here the opportunities for insight in medicine are much greater than in law, because of closer contact of student and teacher in laboratory and clinic and especially in hospital. In the law school much of the instruction is didactic. In law as in medicine the character of the candidate is of crucial importance, and in New York co-operation between school and licensing authority in an effort to determine the character of the applicant has been helpful. In some law schools, however, and especially in the part-time schools, the teachers know practically nothing about

the students in this very important respect. One serious difficulty in determining what kind of lawyer, for example, the candidate will prove to be, is that character development is not complete at the age of twenty-one or twenty-two. Better insight is needed, based on better acquaintance, and the procedure in Pennsylvania will perhaps be helpful. There, each candidate for a law degree is assigned to a practicing lawyer whose duty it is to make a personality study. He may be in a position to do some teaching, especially in giving the right point of view in approaching the practice of law, some evaluating, and some advice and direction. It has been found that a substantial percentage of the candidates are advised not to go on in the course.

A strong plea was made by Father Alphonse M. Schwaltz, of St. Louis, for closer incorporation of the medical school in the university, for both can profit greatly by close association. It is not clear which would profit more, probably varying with conditions, but each has a significant contribution to make to the solution of their common problems. In the association are two dangers: too much federalization and too much individualization. Perhaps the most important field in which the university can be of help is to make clear the social implications and obligations of medicine.

In recent years the problem of specialism in medicine has received considerable attention. It is not new, however, and Dr. Willard C. Rappleye, of New York, noting the proposed requirement of three years of collegiate work before entrance to the medical school, reminded the Congress that if this becomes effective in 1940 it will be on the 800th anniversary of the requirement by Roger, of Sicily, that three years of college work should precede the beginning of the study of medicine in the university of his day. It is interesting to note how thought in one field may fertilize another related field. Study of the needs of the specialist examining boards helps to make clear the needs of graduate education and the need in the specialties for persons with better training in the fundamentals of the undergraduate medical course and in the premedical fields. From this study came Dr. Rappleye's suggestion that for better co-ordination and co-operation of all medical interests there should be formed a national medical council—non governmental in nature, advisory in function—to make a further study of the preparation of the physician for his work. The suggestion is worthy of careful consideration by the whole medical profession and by all persons interested in the future health program of the entire country.

The proposal to limit student enrollment in medical schools always stimulates controversy so that it is difficult to get a consideration of the subject on its merits. Dr. Walter M. Kotschnig, of Smith College, presented an excellent exposition, perhaps because he was not handicapped by being a physician. He pointed out what has been noted before, especially by non medical students of the subject, that while the limitation in a given school may be reasonable if it is based on the real capacity of the school, a general limitation because someone thinks that there are too many doctors has nothing actual to support it, because an accurate determination of how many physicians are needed has never been made. There should be a scientific definition of the demand and some sort of calculation of future demands, which can be at best only an approximation. It may be that some restraint should be exercised, as a result of previously made scientific determinations, but such restraint should be characterized by lack of constraint and should be based on comprehension of all available information. The studies should be made not by but with persons of the professional group, for on ac-

count of possible results, the profession might be regarded as prejudiced in favor of restriction. After all, the greater need is for improvement of the physicians rather than for increase or decrease in their number.

Various limited aspects of the undergraduate teaching of medicine were discussed: clinical medicine by Dr. Burrill O. Raulston, California, preventive medicine by Dr. J. G. FitzGerald, Toronto, obstetrics by Dr. James R. McCord, Georgia, and nutrition by Dr. Salvatore P. Lucia, California.

One morning was devoted to a symposium on graduate medical education, a subject to which more attention has been directed each year recently. If one notes what is done now, compared with fifteen years ago, astonishing progress has been made. But if one considers what the specialist examining boards think advisable in the preparation of their diplomates, one sees that only a beginning has been made. In these discussions the needs of the general practitioner for continued preparation received constant attention.

Two sessions were devoted to problems which especially concern state boards of licensure. Since internships are now taken by over 95 per cent of the graduates of medical schools each year and since there are many more internships available than there are candidates to fill them, it has been suggested that one year of internship be required by law before admission to examination for registration. Twenty states either have already made or will soon make this requirement. At first sight the proposal seems reasonable, but closer study makes it evident that the matter is not so simple as it appears. How much is the internship worth? What kinds of internship are available? What kind of internship is desirable? Two ideas dominate the situation, and they are not immediately compatible without qualification: the internship is for the further education of the physician—the internship is for the purpose of getting some necessary hospital work done.

It is well known that there is exploitation of interns, this follows from the fact that the hospital takes no responsibility for seeing that the intern is given the opportunity to make the most of his experience. In some of the so-called teaching hospitals, that is, those which are identified with medical schools and in which teaching of undergraduate medical students is constantly carried on, carefully planned courses for the training of interns are provided. But such hospitals are relatively few, and if it is difficult to find enough teachers of medicine to man the teaching hospitals, what hope is there that hospitals remote from medical schools will have adequate teachers for interns?

A question on which there is vigorous controversy is the requirement by some boards of registration that the year of internship be on a rotating service. The result is that some states will not accept the one year straight internship, which is the kind of experience received in the teaching hospitals by the best of the recent graduates. To what extent this is militating against the admission to practice in these states of the better grade of physician is not clear, but if the regulation is rigorously enforced, it will undoubtedly have a deleterious effect. In this controversy what is usually forgotten is that the mechanics of education is of less importance than the personal quality of the teacher. The hospitals remote from the medical schools do not as a rule have on their staffs physicians who are interested in teaching. Until hospitals more generally recognize and accept a responsibility for educating the interns, it is generally agreed that it is unwise to require the internship before admission to examination.

The problems presented to state boards of registration

by candidates who have received their medical education abroad and who seek admission to practice in the United States are numerous and vexatious. It is not so much that the standards for admission to practice in foreign countries have been appreciably lowered, but that often the persons who make application for registration in the United States have not been permitted to fulfill all the requirements for entering practice in the country in which the school is situated. Sometimes they have been allowed to take all the courses and examinations but for racial reasons have been refused degrees or have been refused licensure in the country in which they studied. Often clinical opportunities have been restricted to certain groups, or the course given to foreigners has been different and less rigid than that given to nationals. There is urgent need for some uniformity of procedure in evaluating the credentials from foreign medical schools.

One example of what can be done in a limited field was given by Dr. William C. MacTavish, of New York, who in co-operation with a small group of interested persons has been securing information about American students in Italian medical schools. When in 1933 there were published the rulings of the American Medical Association and of the Federation of State Medical Boards with reference to accepting Americans who had studied in foreign medical schools, there was expressed resentment on the part of a considerable element in the Italian-born American population at the alleged reflection on Italian medical schools. It required long-continued, patient and tactful negotiations, in which the official Italian representatives were most co-operative and fair-minded, to reach the present satisfactory arrangement. American students who wish to study medicine in Italian schools are required to file their credentials with the nearest Italian consul. The papers are forwarded to the Italian Consul General in New York and are evaluated by Dr. MacTavish as they would be for an approved medical school in the United States, except that the candidate must show sufficient knowledge of Italian to be able to profit by his study abroad. By this procedure many persons who are unsuited are prevented from going. For the benefit of those who are accepted, sixty-five internships in Italian hospitals are reserved. The Italian authorities have expressed themselves as much gratified with the distinct improvement in the candidates from the United States admitted under the present procedure, as contrasted with those under the previous unsupervised method. It is an example of what can be accomplished by intelligent effort.

There was a symposium on the promulgation of regulations authorized by law, and a resumé of the effects of the basic science law in Minnesota, which include a considerable reduction in the number of new registrants in osteopathy and chiropractic. There is no general agreement that this procedure is the best way of dealing with the problem presented by the cults.

NOTICES

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The American Association for the Study of Goiter, pursuant to its accepted invitation and to correspondence with the honorary presidents and attending members of the First and Second International Goiter Conferences, announces that the Third International Goiter Conference is to convene in Washington, District of Columbia, September 12 to 14.

The subjects proposed for discussion are as indicated in the outlined tentative program given below

Physicians and others in the United States and in other countries desirous of participating in the program are requested to submit titles at their earliest convenience. Since the time which it is possible to allocate on the program is obviously limited, it will be necessary for the Program Committee to exercise its best judgment in the selection of speakers and to insist without exception that the speakers conform to the time allocated

Manuscripts of addresses, papers and discussions delivered or read at the meetings are to be published in extenso in the form of transactions.

The official language of the conference will be English. Interpreters will be furnished for papers read in other languages

For further information concerning the conference, communicate with the chairman of the Program Committee (Allen Graham, M.D., 2020 East 93 Street, Cleveland, Ohio)

* * *

OUTLINE OF TENTATIVE PROGRAM

First Day Subjects Endemic Goiter, Creunism and Myxedema.

Etology	Iodine
Pathology	Prophylaxis
Types	Thyroiditis
Geographic distribution	Malignant goiter

Second Day Subjects The Thyroid in Relation to Metabolism, Nutrition and Endocrine Glands Physiological and pathological interrelation and clinical application

Oxidation	Parathyroid
Sugar metabolism	Pituitary
Water balance	Adrenals

Third Day Subject. Hyperthyroidism.

Basal metabolism	Types	Diffuse toxic goiter
Iodine		Nodular toxic goiter
Complications		
Recurrences	Treatment	Nonsurgical
Goiter heart		Surgical

The subdivisions under the subjects above are for illustrative purposes only and are not to be considered as all inclusive or exclusive.

CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	ORTHOPEDIC CONSULTANT
Lowell	April 1	Albert H. Brewster
Salem	April 4	Harold C. Bean
Haverhill	April 6	Arthur T. Legg
Gardner	April 12	Mark H. Rogers
Brockton	April 14	George W. Van Gorder
Worcester	April 15	John W. O'Meara
Pittsfield	April 18	Francis A. Slowick
Springfield	April 20	Garry deN. Hough, Jr
Fall River	April 25	Eugene A. McCarthy
Hyannis	April 26	Paul L. Norton

NEW BEDFORD CANCER CLINIC

The New Bedford Cancer Clinic in conjunction with the State Cancer Commission will hold a public demonstration clinic of cured cases of cancer at the Outpatient Department of St. Luke's Hospital, New Bedford, on Wednesday, April 13, at 4 00 p m.

All physicians in this district are invited to attend clinic.

CURTIS TRIPP, M.D., *Sec*

TUFTS MEDICAL ALUMNI DINNER

The annual dinner of the Alumni Association of College Medical School will be held Wednesday, 30, at 7 00 p m at the Copley Plaza Hotel, Boston. For reservations call Hub 9670

ROBERT T. PHILLIPS, M.D., *Sec*

MASSACHUSETTS MEMORIAL HOSPITALS

The annual reunion of the House Officers Association of the Massachusetts Memorial Hospitals held on Saturday, April 23, at 10 00 a m. in the Co Memorial Building

WELMAN B. CHRISTIE, M.D., *Secretary-Treas*

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital, on March 28, at 8 15 p m.

PROGRAM

The Incidence of the Criteria of Allergy in Cases of Asthma. Dr Hyman Morrison.
The Significance of Electrocardiographic Changes in Attacks of Angina Pectoris. Dr Joseph E. F. R.
The Relation of Blood Pigment Metabolism to the Change in Blood Volume in Congestive Heart Failure. John Waller.
The Effect of Digitalis in Partial Heart Block. Dr D. Altschule.
The Clinical and Pathological Manifestations of Coronary Arterial Disease as Disclosed by Injection Plus Angiogram Studies. Dr David Davis.
The Breath-Holding Test: A simple standard test for blood pressure. Dr David Aymon.
Cardiac Cirrhosis. Dr Herrman L. Blumgart.
Interested physicians and medical students are invited to attend.

JAMES M. FAULKNER, M.D., *Secretary*

HAMPSHIRE DISTRICT MEDICAL SOCIETY

The annual meeting of the Hampshire District Medical Society will be held at the Dickinson Hospital, Northampton, on Wednesday, May 11, at 11 30 a m.

JOSEPH D. COLLINS, M.D., *Secretary*

BOSTON SOCIETY FOR THE ADVANCEMENT OF GASTROENTEROLOGY

The next meeting of the Boston Society for the Advancement of Gastroenterology will be held at the Carney Hospital, on Wednesday, March 30, at 12 o'clock noon.

Case demonstrations will be given by Drs. Louis F. Ran, A. McKay Fraser, William E. Browne, Ed Leonard and Norman A. Welch, of the medical surgical staffs.

Physicians, medical students and nurses are cordially invited to attend.

CHARLES W. McCURE, M.D., *Secretary*

THE JOHN T. BOTTOMLEY SOCIETY

The John T. Bottomley Society of the Carney Hospital Outpatient Department will hold its regular monthly meeting on Tuesday, April 5, at 11.30 a m.

Dr Laurence McGrath will speak on "Allergy"

WILLIAM J. MACDONALD, M.D., *Secretary*

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high voltage x ray.

Physicians are welcome to visit this clinic and bring a patient to the clinic for diagnosis.

RADIO BROADCASTS

The seventh group of weekly broadcasts sponsored by the American Medical Association and the National Broadcasting Company concern health education. These dramatized health messages are intended to furnish supplementary material for health teaching in junior and senior high schools and are broadcast every Wednesday from 2:00 to 2:30 p. m. over the Red Network. The dates and subjects are as follows:

March 30—A Fool for a Day. Fallacies and popular beliefs that are not true and that influence behavior in a manner detrimental to health.

April 6—Living with People. Elements of mental hygiene, getting along with people, adjustment to the environment.

April 13—It May Happen to You. Accidents in the home and on the highway and ways to avoid them.

April 20—Who Chooses Your Doctor? The characteristics of a reputable physician as distinguished from quacks, fakers, faddists or exploiters.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MARCH 28

MONDAY MARCH 28

8:15 p. m. New England Heart Association. Beth Israel Hospital

TUESDAY MARCH 29

*9-10 a. m. Boston Dispensary. A Clinical Evaluation of the Blood Sedimentation Rate as a Routine Diagnostic Procedure. Dr. Elbert B. Agner

*10 a. m. 1:30 p. m. Tumor clinic. Boston Dispensary

WEDNESDAY MARCH 30

*9-10 a. m. Boston Dispensary. Hospital case presentation. Dr. S. J. Thannhauser

12 m. Clinicopathological conference. Children's Hospital amphitheater

12 m. Boston Society for the Advancement of Gastroenterology. Carney Hospital.

7 p. m. Tufts Medical Alumni Dinner. Copley Plaza Hotel Boston

THURSDAY MARCH 31

8:30-9:30 a. m. Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals, held this week at the Children's Hospital

*9-10 a. m. Boston Dispensary. Interesting Clinical Problems from the District Service. Dr. Isidore Olef.

FRIDAY APRIL 1

*9-10 a. m. Boston Dispensary. Specific Therapy for Certain Anemias of Childhood. Dr. Louis K. Diamond.

10 a. m. 12:30 p. m. Tumor clinic. Boston Dispensary

12 m. Clinical meeting of the Children's Medical Service, Massachusetts General Hospital. Ether Dome.

SATURDAY APRIL 2

*9-10 a. m. Boston Dispensary. Pneumonia. Dr. Joseph H. Pratt

10 a. m. 12 m. Staff rounds at the Peter Bent Brigham Hospital. Conducted by Dr. Henry A. Christian.

SUNDAY APRIL 3

4 p. m. Illustrated public health lecture, Faulkner Hospital auditorium. Nerves and Their Relation to Insanity. Dr. Merrill Moore.

Open to the medical profession.

MARCH 25—Staff meeting of the Massachusetts Memorial Hospitals. 8:15 p. m.

MARCH 28—New England Heart Association. Page 546.

MARCH 28 APRIL 1—Postgraduate Institute of the Philadelphia County Medical Society. Page 282. Issue of February 10.

MARCH 30—Tufts Medical Alumni Dinner. Page 546.

MARCH 30—Boston Society for the Advancement of Gastroenterology. Page 546.

APRIL 13—Springfield District Teaching Clinics. Page 499. Issue of March 17.

APRIL 4-8—The American College of Physicians. Page 41. Issue of July 1.

APRIL 5—Greater Boston Medical Society. 8:30 p. m. auditorium of Beth Israel Hospital Boston.

APRIL 5—John T. Bottomley Society. Page 546.

APRIL 13—New Bedford Cancer Clinic. Page 546.

APRIL 13—Eastern Hampden Medical Association. Page 499. Issue of March 17.

APRIL 14—Pentucket Association of Physicians. Hotel Bartlett, 95 Main Street Haverhill. 8:30 p. m.

APRIL 13—Boston Medical History Club. Boston Medical Library. 8 Fenway Boston.

APRIL 18, 19 and 20—Thomas William Salmon Memorial Lectures. Page 450. Issue of March 10.

APRIL 23—Massachusetts Memorial Hospitals, annual reunion of house officers alumni association. Page 546.

APRIL 26—New England Society of Psychiatry. Page 322. Issue of February 17.

MAY 31, JUNE 1 and 2—Annual meeting of the Massachusetts Medical Society. Hotel Bradford Boston.

JUNE 6, 7, 8, and 9—American Association of Industrial Physicians. Page 499. Issue of March 17.

JUNE 13-17—American Medical Association. San Francisco.

JUNE 13, OCTOBER 3 and NOVEMBER 15—American Board of Ophthalmology. Page 282. Issue of February 10.

SEPTEMBER 12-14—American Association for the Study of Gout. Page 545.

OCTOBER 17-21—Clinical Congress of the American College of Surgeons, New York City.

OCTOBER 24-26—Academy of Physical Medicine Scientific Session. Washington D. C.

DISTRICT MEDICAL SOCIETIES

BRISTOL SOUTH

MAY 5—5 p. m. New Bedford.

ESSEX SOUTH

APRIL 6—Gloucester Hospital Gloucester. Clinic at 5 p. m. Dinner at 7 p. m. Speaker and subject to be announced.

MAY 5—Censors meet at Salem Hospital, 3:30 p. m.

MAY 11—Annual meeting Salem Country Club Peabody. Dinner at 7 p. m. Speaker and subject to be announced.

FRANKLIN

Meeting will be held at the Franklin County Hospital Greenfield, at 11 a. m. the second Tuesday of May.

HAMPTON

Meetings will be held on the fourth Tuesday in April and July.

HAMPSHIRE

MAY 11—Page 546.

MIDDLESEX EAST

Meeting will be held at the Bear Hill Golf Club, Stoneham at 12:15 p. m. on May 11.

MIDDLESEX NORTH

Meeting will be held at the Vesper Country Club Lowell on April 27.

NORFOLK DISTRICT

MARCH 29—Page 500. Issue of March 17.

MAY—Annual meeting.

The censors meet on the first Thursdays of May and November in each year.

NORFOLK SOUTH

Meetings held at 12 noon.

APRIL 7—At the Quincy City Hospital.

MAY 5—Annual meeting.

PLYMOUTH

Meetings will be held at 11 a. m. on April 21, May 19 and July 21.

WORCESTER

APRIL 13—Hahnemann Hospital, Worcester. Dinner will be at 6:15 to be followed by business session and scientific program.

MAY 11—Afternoon and evening, annual meeting. Place and schedule of program to be announced.

BOOK REVIEWS

Diathermy Including diathermotherapy and other forms of medical and surgical electrothermic treatment Elkin P. Cumberbatch. Third edition 576 pp. Baltimore: William Wood & Company, 1937 \$6.00

The author of this book, an Englishman, is one of the few living men who have worked with electrotherapy from its beginning. He is thoroughly conversant with diathermy of the "long wave" (300 meter wavelength) type, which uses metal electrodes in contact with the body. A large portion of the book is devoted to that type of current. Unfortunately, this procedure is being used less and less, and manufacturers in this country have practically stopped making such machines.

The book is divided into three parts: (1) "Physical and Electrotechnical Principles," (2) "Medical Electrothermic Methods and Their Uses," (3) "Surgical Electrothermic Methods and Their Uses." The chapters dealing with the physics of the high-frequency currents, largely written by Dr. H. J. Taylor, physicist to the Institute of Physical Medicine, are excellent for those desirous of knowing how high frequency apparatus is made and what may be expected by its use. Unreasonable space has been allotted to subjects which would be clearer and more readable if fewer pages had been written. For instance, a chapter of forty pages is devoted to a discussion of recorded body temperatures following the long-wave type of diathermy. Three hundred and ten of the five hundred and fifty pages are devoted to long-wave diathermy and its relation to medical procedures. The balance deals with surgical procedures, largely by the older method. Only fifty pages are given to theory and an inadequate allusion to the short wave diathermy.

There is much repetition occurring throughout. Far too much space has been allotted to the elementary details, while frequently not enough definite scientific information has been given to more important aspects. It is thoroughly unsatisfactory as a textbook on diathermy here in America where we have largely discarded long wave diathermy and are bending our energies toward proving what seems to be advantageous in the short-wave field.

The real usefulness of this book lies in the help it offers teachers in obtaining details of the history of high-frequency currents, some of their applications, and—perhaps most important of all—their physics.

Alcohol One man's meat Edward A. Strecker and Francis T. Chambers, Jr. 230 pp. New York: The Macmillan Company, 1938 \$2.50

This is a volume written by Dr. Strecker with the assistance of a former patient. It approaches the problem from a psychological aspect, which method of attack is in accord with the best medical opinion of the day. The treatment of alcoholism is a matter for the attention of a psychiatrist preferably, yet regularly all medical men are confronted with the problem of how to handle situations in which the abuse of alcohol looms large.

Normal and abnormal drinkers are discussed and the drives motivating them are examined in terms of adjustment, not to alcohol itself but rather to the background of the drinker. The inheritance of a nervous system which is non-resistant to alcohol is not held a bar, by the authors, to a routine of activity and achievement. It is their contention that there are no half-measures possible for the alcoholic. He must avoid even a single drink

since his resistance, but not necessarily his physiological tolerance, is so much below the average man's threshold.

Approximately one half the book is devoted to a discussion of the treatment of alcoholism. Acknowledgment is made to the late Richard Peabody, of Boston, and the lines laid out for a therapeutic rationale closely approach those devised by him.

Manual of Clinical and Laboratory Technic Hiram B. Weiss and Raphael Isaacs. Fifth edition, reset. 141 pp. Philadelphia and London: W. B. Saunders Company, 1937 \$1.50

This is an unusually fine little book, remarkable for the completeness with which it covers the whole field of medical examination, and showing a mastery of medicine by the authors which has come from years of experience in the laboratory and the clinic. In its fifth edition it should continue to prove useful to student, intern and practitioner.

One of its features is that it includes the newer tests not yet available in the standard textbooks and found only in current periodical literature. Among the material added in this edition are additional tests for Bence Jones substance, methods of counting cellular elements and of measuring the amount of vitamin C in the urine, a graph for the conversion of percentage of hemoglobin to grams, methods of calculation of various blood indices, new methods for determining the clotting and retraction times of the blood, a listing of the characteristics of the blood in pyogenic infection, methods of measuring the diameter and volume of the red-blood cells, and of oxidase staining, the technic of the sheep-cell agglutination test in infectious mononucleosis, of hydrogen-ion concentration determinations of gastric juice and of the Neufeld reaction for pneumococcus types, methods of counting the cells of the saliva and of the bone marrow, descriptions of the Nonne-Apel reaction, liver function tests, the Takata-Ara reaction, the technic for determining the albumin-globulin ratio in blood serum, and for making the Congo red test for amyloidosis and diagnostic tests for undulant fever. The normal standards for each test are given, and certain details in the interpretation of tests and their clinical application are discussed. A comprehensive table of nutritive values of foods and a complete index add to the value of this manual.

A Practical Treatise on Diseases of the Skin For the use of students and practitioners Oliver S. Ormsby. Fifth edition, thoroughly revised. 1334 pp. Philadelphia: Lea & Febiger, 1937 \$12.00

All students of dermatology will be interested in this new edition of "Diseases of the Skin." Whereas the greater part of the material is essentially the same as in the previous edition, twenty new diseases have been described, and other material has been rewritten. New illustrations have been added, principally photomicrographs, which is indication of the growing interest in the pathology of dermatology.

The mycologic side is treated as fully as could be expected in a work of this scope. Sabouraud's standard classification of the tinea is given, but no reference is made to the newer attempts at classification.

This book is a vast storehouse of description of disease, etiology, differential diagnosis and treatment. Its possessor may feel himself fortunate in having so much information in one volume, which is easily available. A very complete bibliography is provided.

NUMBER 13

WRINGER ARM

A Report of Twenty-Six Cases

DONALD W. MACCOLLUM, M.D.*

BOSTON

MANY of the terms describing entities in medicine depend largely on Latin or Greek for their derivation, so that one word is often a succinct descriptive expression of a recognized syndrome. It is of interest to note that occasionally a particular disease or accident becomes so intimately associated with its causative agent that an idiomatic, though not entirely scientific, term which soon becomes acceptable to the medical mind, is applied to it. Examples of the latter are frequent.

With the advent of the automobile came the chauffeur's fracture which, in turn, has become more and more of a rarity with the invention of the self-starter. Similarly, the electric waxer, the mechanical loom and the silent policeman have resulted, respectively, in the now relatively infrequent occurrence of housemaid's knee, weaver's bottom and policeman's heel. At present, riveter's wrist, tennis elbow, baseball finger, bumper fracture, park-bench paralysis and writer's cramp have become unofficial diagnostic terms. Into this same category falls one more, previously undescribed, which I shall designate as "wringer arm."

In the days when clotheswringers were turned by hand, a pinched finger or a crushed thumb was often encountered, but seldom was an entire arm drawn between the rollers. With the progress in mechanization, however, the invention of the electric clotheswringer so appealed to the public that over thirteen million of these machines are estimated to be in use in the United States†. One result of this popularity has been a series of accidents to small children. The steady increase in the frequency of such arm injuries parallels the increase in sales (Table 1).

The turning rollers fascinate the child and lure him to closer investigation. In spite of the numer-

ous safety devices which have been developed on some wringers, there are none to prevent the fingers' being caught. Once they are engaged, the entire arm is usually pulled between the rollers so suddenly and with such force that the child is unable to extricate himself. He is found screaming with pain and from fright, with the rollers churning away in his axilla. If the mother keeps her head

Table 1 The frequency of wringer arm injuries shows the same general curve as that of the number of electric wringers sold in the United States

she will strike the safety release and liberate the arm. Very frequently, however, her first impulse is to reverse the direction of the rollers and exert countertraction upon the child, thus subjecting the arm to a second crushing.

This accident may occur in all age groups, but is most frequent in early childhood. In this series

*Personal communication from the American Washing Machine Manufacturers Association, Chicago, Illinois.

of 26 cases, the age of the patients varied from one to seven. Twenty-two accidents occurred in children between two and five. Over twice as many boys as girls were injured.

The extent of the injury is variable, dependent upon the speed of the machine, the gap between the rollers and the length of time that the arm is subjected to crushing. If the child is young the injury may be less severe on account of the elasticity of the soft tissue and the flexibility of the ligaments and joints. In none of the cases in this series were there demonstrable nerve injuries. There were minor fractures in only 2 cases, a green-stick fracture of the ulna, and a subperiosteal crack in the proximal phalanx of the fifth finger. The primary trauma in every case was to the skin, subcutaneous tissues and muscles. In each instance there were marked ecchymosis, edema of the subcutaneous tissues and abrasions of the skin. Three patients received lacerations which required suturing (Figs 1, 2A and 2B). In several others there were diffuse hematomas beneath the skin or in the muscles. One of the hematomas required aspiration, the others gradually resolved. In the 7 most severely injured patients there was sufficient trauma to cause necrosis of the skin and underlying tissues. After these areas sloughed, plastic surgery was required for repair of the defects.

Because of the infrequency of this accident in the same home or in the same neighborhood, there is fortunately no standard home remedy that is employed before the doctor is called. In reality, witnesses to this accident generally think that the injury is much more severe than it actually is. Because of the parents' concern, the patient is usually seen by the doctor from fifteen minutes to an hour after his injury. At this time he has usually recovered from the shock of the accident. Even at this stage, the arm is apt to be markedly swollen, with many abrasions distributed over the injured portion (Fig 1). The intact skin is usually blotchy and shows evidence of interstitial hematomas, edema and areas of residual ischemia caused by injury to the vessel walls. In some cases there is definite subcutaneous crepitation. This is thought to be caused by destruction of the cell walls and bleeding in the fatty layer. It is not, as might be supposed, produced either by air beneath the skin or by injury to the bone. It must be emphasized that the extent of the injury to the soft parts cannot be properly evaluated at this first examination, so that the prognosis at this time must be guarded. Examination for fracture at the initial examination is difficult because of the swelling and tenderness, so that in every case an x-ray

photograph should be taken. If a fracture exists, extreme care must be used in the application of splints to avoid an ischemic paralysis. In the 2 cases of fracture in this series the associated injuries to the soft parts were of more importance and required more attention than the fractures, so that no splints were applied.

The treatment of the fresh injury differs from the treatment of one that is several days old. If the patient is seen shortly after the accident the arm

Figure 1 Case 1, a boy of twenty months. The photograph shows the marked edema and ecchymosis of the right arm only two hours after injury. A bandage covers a small laceration of the thumb.

must first be immobilized either by a sling or by sandbags. The edema must be reduced as rapidly as possible. To accomplish this, iced packs of concentrated magnesium sulfate are applied continuously for the first twenty-four hours. For the second twenty-four hours, these packs are alternated every two hours with hot magnesium-sulfate packs. If there has been extensive maceration of the skin, dry heat may be used alternately with the cold packs. A rigid aseptic technic must be carried out in the treatment of the abrasions. These should be properly cleansed with antiseptic solutions and kept from contamination. This is of extreme importance because sepsis developing in this devitalized tissue may endanger the patient's life from a resulting septicemia. In this series, 6 patients treated ineffectually for several days at home entered the hospital suffering from a septicemia due to a hemolytic streptococcus. All recovered, but in

each case the infection had destroyed tissue over the arm and thus delayed the local healing

When the patient is seen several days after the accident, he may be found to be recovering from

sick, and the temperature is elevated. When cellulitis exists, packs of hot normal saline or boric acid are applied continuously until the infection subsides. The patient's general condition is improved with transfusions and intravenous injections of glucose and saline. In recent cases in this series that were infected with hemolytic streptococci, sulfanilamide has been given with good effect. In

the injury without sequelae. More often, however, two complications are found, alone or in combination the entire arm is swollen, red and painful, with evidence of diffuse cellulitis, or an area of necrosis has developed. The child is usually

Photograph C shows the result six months after grafting.

all cases with cellulitis of the arm but without necrosis, the infection cleared with these measures. In cases with necrosis further treatment was necessary to effect healing.

Necrosis with sloughing of the devitalized tissue is slow in developing, making it almost impossible to judge at the first examination the severity of the injury to the soft parts. If the treatment outlined for fresh injuries is followed closely with the view to the reduction of the edema and the re-establishment of the normal circulation, a minimal

amount of sloughing will occur. In this series, necrosis occurred in 7 cases. Only 1 of these was seen shortly after the accident. The other 6 patients came to the hospital for treatment as late as six weeks afterward. When a dusky

ecchymotic area appears to be growing blacker, the ice packs are discontinued and hot packs are substituted. Light massage and passive movement may be indicated in selected cases. Although it has not been used in this group, the peripheral suction-pressure pump may be of value in aiding the circulatory return.

If the injured tissue does not respond to the

efforts made to revive it, the gangrenous portion will soon become demarcated from the viable portion. Figures 3A and 5A illustrate the typical appearance of an early slough. The edges will gradually retract from the normal skin, and the dead tissue will slowly fall away. It is unwise to perform an operative debridement at this stage because of the surgeon's inability to judge the depth of the slough; he may either remove it in completely and thereby accomplish little, or needlessly remove or injure normal viable tissue. Continued soaks in sterile saline or boric acid will accomplish the removal effectively. During this stage it is advisable to have a tourniquet and a sterile tray with gauze and arterial clips at hand. Although the thrombosis of the vessels is the cause of the necrosis, a severe hemorrhage may result from the sloughing of a deeper vessel that is in completely occluded. In all these cases the patient's blood should be typed and cross-matched with a suitable donor in preparation for such an emergency.

After the dead tissue has been removed, the site of the necrosis usually becomes cratered and covered with a thin layer of pale pink, chronically infected granulations. Figure 5B shows the appearance of the arm shortly after removal of the slough.

At this time the method for filling in this defect must be decided upon, and a correct evaluation of the amount and type of tissue that has been destroyed becomes necessary. In order to ensure the best functional and cosmetic result, all this tissue should be replaced. Replacement of subcutaneous tissue, fat and skin, if necessary, must be done by means of either a pedicle or an advancement flap of the neighboring tissue. To carry out either of these procedures at this time would be unwise because of the lowered resistance of the patient and of the decreased vitality of the skin in the immediate vicinity of the defect. When a flap is used, the low-grade sepsis which is almost invariably present in the recipient site causes a separation of the suture lines and a loss of part or all the flap. For this reason it has been found advisable to cover the raw surface with epithelium in the form of thick razor grafts. If contractures develop that cannot be remedied by exercise and massage, a pedicled flap can be utilized at a later date when it is possible to carry out the procedure in an aseptic field and at a time more advantageous for good healing. Case 5 (Fig 5) shows the result of an extensive slough over about one third of the arm. It appears that razor grafts on this site would not have sufficed to have prevented late contractures from the scar. Lymphedema of the

hand and limitation of movements were expected. However, neither in this case nor in any of the others in this series has it been found necessary

to do a subsequent graft. These results were exceptionally fortunate, and severe injuries such as those in Cases 4, 5 and 6 are likely to require the replacement of the subcutaneous tissue.

The technic of razor-grafting for unhealed burns

has recently been described by the author.¹ The same principles apply to crushing injuries, but certain variations are necessary to produce a good result. It must be remembered that there has been an extensive injury to the tissue surrounding the granulating area to be covered by the grafts (Fig. 3A, 4A and 5A). Because of this, the blood supply to the raw area is reduced and lymphatic drainage is impaired, so that the re-

A

Figure 6 Case 6 a girl of six years. Photograph A taken six weeks after the accident when she was seen for the first time shows the extensive raw area resulting from a combination of pressure necrosis and burn as this patient caught her arm in a hot triangle. Photograph B shows the result four weeks after the application of razor grafts. This patient is still under treatment.

ipient site becomes similar in many ways to that caused by an electric burn. The granulations are slow in forming and in becoming clean enough for grafting. To ensure a successful take of the graft it is necessary that the preoperative treatment be centered upon hastening the formation of healthy granulating tissue. The preoperative routine followed at the Children's Hospital is as follows:

The arm is given a daily bath of hypertonic saline for thirty minutes. The raw area is then

covered by Tulle Gras—wide-meshed paraffined gauze which has been impregnated with vaseline containing 1 per cent compound tincture of benzoin, and which has been autoclaved for forty-five minutes under 15 pounds' pressure. Over this gauze are placed gauze sponges soaked in Eusol, composed of boric acid 12.5 gm and chlorinated lime 12.5 gm in 1000 cc of water, which is allowed to stand for twelve hours and is then filtered. It is usually too powerful to apply undiluted, so that it should be emulsified with an equal amount of mineral oil. Dry gauze is placed over these dressings, which are held in position by a firmly applied elastic bandage. It is important that the arm be bandaged tightly enough to keep the granulations flattened, but not so tightly as to impair the circulation. In order to prevent the hand and fingers from becoming edematous, the elastic bandage should be started at the fingertips and carried up evenly to the axilla. If only a section of the arm is covered, the part distal to the bandage will become swollen and painful. In addition to these dressings, the arm should be immobilized with padded splints or sandbags. Plaster casts are to be avoided.

When the raw area has become cherry-pink and the patient is sufficiently improved to withstand the operative procedure, the case is ready for grafting. The patient is given a general anesthetic, and both donor and recipient areas are cleansed with soap and water, alcohol, and ether. The recipient site is prepared first. The granulations, together with their fibrous tissue base, are removed down to the normal subcutaneous tissue. Bleeding is controlled by arterial clips and by hot saline packs. Ligatures and all other foreign material are to be avoided.

A pattern of the defect is then made by pressing a dry, unbleached cotton cloth on the recipient site, when its contour will be outlined by a blood stain. The cloth is then inverted and covered with sheets of Tulle Gras. The grafts are cut and laid raw side up on the meshed pattern so that the edge of each will overlap its neighbor by 1 or 2 mm. The entire pattern is then transferred to the recipient area. The edges of the mesh pattern

are sutured to the normal skin to prevent the grafts from being displaced when the dressing is applied. A pressure dressing is next applied over the grafts. A gauze pad exactly the size and shape of the pattern is fixed evenly and securely to the recipient site by an elastic mesh bandage. Over this is placed more gauze, held in position by elastic adhesive and elastic crepe bandage. Here also the bandage should begin at the fingertips to avoid edema of the most distal portion. The arm is then immobilized in splints, care being taken to prevent rotation of the shoulder.

The dressings are first changed on the seventh or eighth postoperative day. By that time the area is usually completely healed, but protective dressings are needed for another week. Then active physiotherapy and occupational therapy may be started. Even in this age group the long immobilization results in a marked stiffness of the joints and muscles. The degree of impairment of function is much greater than that usually found where burns or fractures have been immobilized for the same length of time. The reason is not clear; it may be a fibrosis in the muscles resulting from either a mild degree of ischemia following injury or the organization of a hematoma. Exercise under water is of great benefit for hastening normal mobility, and may easily be carried out at home in the bathtub. Within six months the motion of all joints should be normal. The subcutaneous tissue proliferates beneath the graft and obliterates the depression caused by the original loss of tissue. If the grafting has been properly done, the surface smooths out and gives a good cosmetic effect.

SUMMARY

A series of 26 wringer-arm injuries is presented.

The immediate and late treatment of these injuries is outlined.

The variations in the technic of razor grafting used are briefly discussed.

THE APICAL CHEST LEAD AS THE CHIEF AID IN THE DIAGNOSIS OF CORONARY OCCLUSION

HOWARD B SPRAGUE, M.D.,* AND SYLVESTER MCGINN, M.D.†

BOSTON

THE most definite advance in electrocardiography in many years has been the introduction of the recording of the electrocardiogram from lead points on the chest over the heart. For renewing the work in this subject in its clinical and experimental applications, we are indebted to Wolferth, Wood and their associates^{1, 2, 3}. The skepticism of five years ago as to its value in the diagnosis of coronary thrombosis gave way later to some overenthusiasm and the attribution to the chest lead of an ability to give specific information not possessed by the standard limb leads. As Roth⁴ has pointed out, there has been a tendency to disregard some of the obvious

Figure 1 Normal Lead 4, with the right-arm electrode placed over the apex of the heart and the indifferent electrode on the left leg

abnormalities in the standard leads in this concentration on the new precordial records. It was with this idea in mind that we chose the title of this paper, and for illustration we present a series of cases in which the chest lead was the *chief* electrocardiographic aid, while admitting that the limb leads were by no means always normal.

Until June, 1937, the routine connection of the electrocardiograph for the chest lead at the Massachusetts General Hospital was through the Lead-2 wires—the right-arm electrode placed over the cardiac apex and the left-leg connection used as the indifferent electrode. This lead will be called Lead 4 in our discussion (Fig. 1). At present the left-leg electrode is placed at the apex and the left arm is the indifferent lead point. One of the cases reported here shows a chest-lead electrocardiogram taken with this technique.

*Instructor in medicine (Courses for Graduates) Harvard Medical School associate physician, Massachusetts General Hospital.

†Instructor in medicine (Courses for Graduates) Harvard Medical School assistant in medicine, Massachusetts General Hospital.

⁴This connection of electrodes reverses the polarity and the T wave is normally upright. The left leg is perhaps a somewhat better indifferent lead point than the left arm and is now used at the Massachusetts General Hospital (March, 1938).

Ninety-two patients with coronary thrombosis, recent or old, were seen by us, both standard and chest leads were recorded, and 16 cases were selected as showing in electrocardiograms evidence in Lead 4 unobtainable in the axial leads. In 1000 consecutive electrocardiograms at the Massachusetts General Hospital, 16 cases of coronary thrombosis were found, 3 being selected as representative of the value of Lead 4, and 2 other cases were found in the hospital files. There were therefore 21 cases in which Lead 4 was at some time in the course of coronary thrombosis the chief aid to the diagnosis. In this entire series the infarct was of the anterior type, as determined by the electrocardiogram, and our observations refer at this time to this type only. In 2 cases autopsy study was possible and was confirmatory.

The cases were divided into two groups, Group I comprising 14 in which Lead 4 showed the only positive evidence of *acute* coronary occlusion. In 12 cases changes were found in the conventional leads of the electrocardiograms that suggested the diagnosis but were insufficient to clinch it. They consisted of diphasic T waves in Lead 1 in 8 cases, associated with a very slight elevation of the S-T segment in half of them, low T waves and isoelectric T waves in Leads 1 and 2 in 2 cases, a sagging S-T segment in Lead 1 in 1 case, and bundle-branch block in 1. Four patients had had digitalis, and 11 had suffered from angina pectoris from 2 weeks to 2 years before the most recent coronary occlusion.

The changes noted in Lead 4 of Group 1 were found at intervals varying from twelve hours to eight days after the occlusion. There were 8 cases in which the Q wave was absent and in which the S-T segment was displaced downward, the T wave then went above the base line in most cases in a diphasic form. Three tracings showed upright T waves in Lead 4 and in 2 of these the Q waves disappeared three and six weeks later respectively. The T wave was diphasic with an early inversion in 1 case, and in 2 the Q waves were absent but the T waves were normal. These observations suggest that the commonest early change is a diphasic T wave with low origin of the S-T segment and absent Q waves, although it is not unusual to find upright T waves with the Q waves disappearing at a later time.

There were placed in Group II 10 cases in which Lead 4 showed the only definite evidence of a *previous* coronary occlusion. Six of these had changes in the conventional leads that might have suggested a previous occlusion, but they were indefinite. They were as follows: 3 tracings with sagging S-T intervals in Lead 1, 2 with diphasic T waves in Lead 1 and isoelectric T waves in Lead 2, and 1 with a low T wave in Lead 1. One patient had been taking digitals, and 5 patients had had angina pectoris for from two weeks to six years.

ties in Lead 4 in the presence of essentially negative conventional leads, in tracings taken eight, twenty and thirty days after the acute occlusion. These cases were also included in Group I as showing the most definite evidence of coronary occlusion in Lead 4. Two cases showed a diphasic T wave of low origin with the upward phase predominating—1 with an absent Q wave and 1 with a small upward Q wave. In the remaining case the Q wave was absent and there was an early inversion of the T wave. The most recent electrocardiogram of the case with the upward Q wave shows an absence of

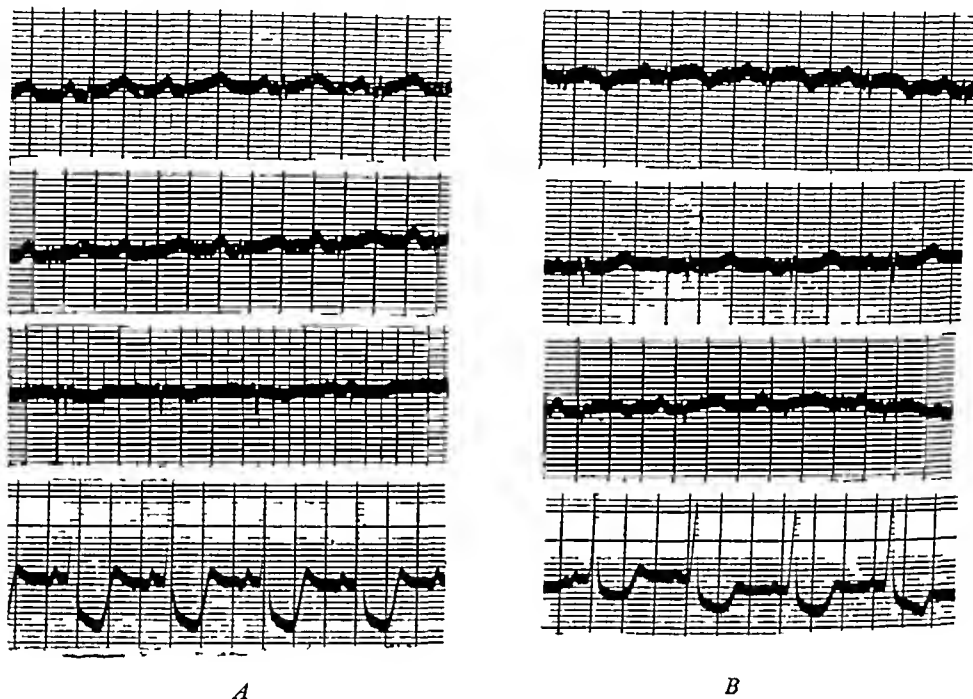

Figure 2. Case 1
A Six days after occlusion
B Fourteen days after occlusion

The changes found in Lead 4 followed coronary occlusions in 2 cases at intervals of one and three days respectively, and the intervals in the remaining cases varied from six weeks to two years. The reason for including the 2 acute cases in this group is that the axial leads had returned so far toward normal as to be much less diagnostic than was the chest lead. The commonest finding was an upright T wave in Lead 4 in 5 cases, 2 of which had an upright Q wave. In 1 case there was a high origin of the S-T segment. The Q wave was absent in 2 cases, 1 of which was associated with an early inversion of the T wave. These findings indicate that the T-wave changes persist longer than do the abnormalities of the Q wave, however, there were cases showing that this is not necessarily true.

Three of the Group II cases showed abnormali-

ties in Lead 4 in the presence of essentially negative conventional leads, in tracings taken eight, twenty and thirty days after the acute coronary occlusion.

There were 2 cases which showed points of interest and importance. The electrocardiogram of the first patient showed normal conventional and chest leads two years after a coronary occlusion, despite the autopsy finding of an old myocardial area of infarction involving the interventricular septum and an area of the left ventricle in the region of the apex. The other patient had been suffering from angina, caused by the slightest exertion and lasting for unusually long periods. After several weeks an electrocardiogram was made and a definitely abnormal Lead 4 was found. Eight days later he showed definite clinical evidence of an acute coronary occlusion with a fall in blood pressure, pericardial friction rub and collapse. Ap-

parently he had been suffering from an impending coronary thrombosis or myocardial anoxemia, the only definite evidence of which was shown in the high origin of a very tall T wave in Lead 4

CONCLUSIONS

Serial three-lead electrocardiograms, taken during the course of acute coronary closure, will in almost every case furnish adequate diagnostic evidence of the disease. If, as is often true in non-hospitalized patients or in patients who have recovered from an acute attack, a single electrocardiogram must be relied upon for a definite diag-

CASE REPORTS

Case 1 M E, a 54-year-old woman, gave a history of dyspnea on exertion for many years. Five months before admission on January 18, 1935, she began having pressure in her chest and numbness in the left arm, caused by exertion and relieved by rest. Three days before admission she had a similar pain, which persisted. Physical examination showed marked gallop rhythm, cardiac en-

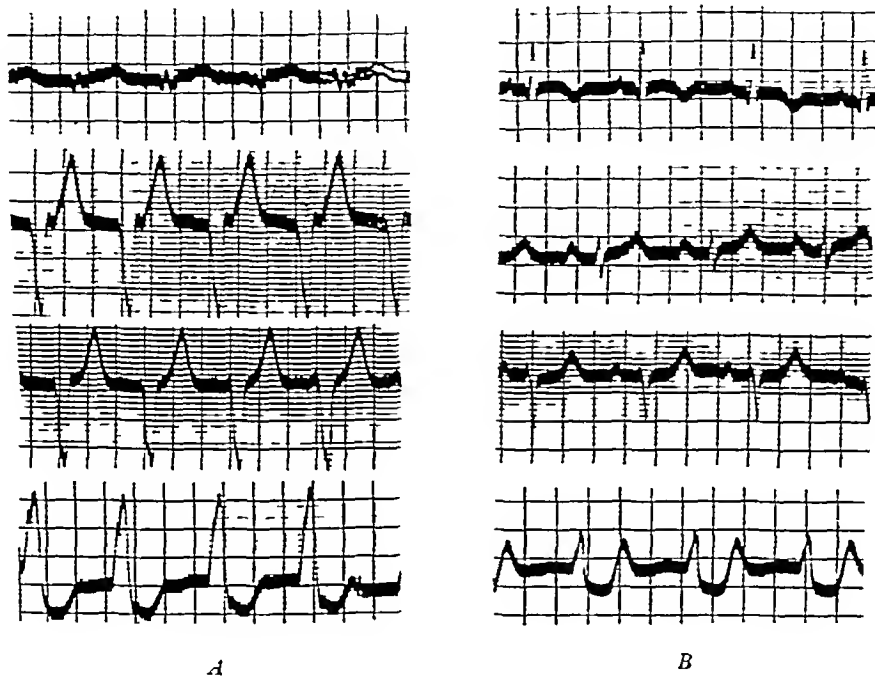

Figure 3 Case 2

B Two days after occlusion

nosis, the evidence from the limb-lead electrocardiograms is likely to be equivocal. Our figures indicate that in nearly 20 per cent of an unselected group of cases with old and fresh infarcts the direct lead from the cardiac apex greatly increased the specificity of the electrocardiographic information. This information is thus immediate. It is confirmatory of the clinical story, and is often of primary value in treatment and prognosis. Inasmuch as the evidence from Lead 4 may precede that from the limb leads or may persist after the latter has disappeared, the precordial lead should be routinely taken in all cases of coronary disease.

largement, no murmurs or evidence of congestive failure and a blood pressure 140/85. Her temperature was 103 F and the white-cell count was 16,400. After 6 weeks observation she was sent back to her doctor improved.

Figure 2A shows that six days after coronary occlusion the axial leads showed only low voltage as an abnormal finding. Lead 4, however, distinctly displayed the diagnostic evidence of anterior cardiac infarction through the displacement of the S-T segment and absent Q wave. The tracing taken fourteen days after the thrombosis (Fig 2B) finally confirms Lead 4 by showing the characteristic inversion of the T wave in Lead 1.

Case 2 J H, a 56-year-old man had been in good health until 3 weeks before admission to the hospital when he complained of tight low substernal pain, caused by walking and relieved by rest. Eight hours before his admission on April 6, 1937, he was awakened with severe constant low substernal pain, weakness, dizziness and sweating. His temperature was 101 F. There were no

Figure 4 Case 2

A Three days after occlusion

B Eight days after occlusion

Figure 5 Case 3 Eighteen days before occlusion

murmurs or congestive failure. The blood pressure on admission was 180/100, but in a few hours it fell to 120/78. The white-cell count was 14,000. After 3 weeks he was discharged to his family physician.

Figure 6 Case 3 Forty-one hours after occlusion. This Lead 4 was made by the new technic, in which the left-leg electrode is placed over the apex of the heart and the indifferent electrode on the left arm.

In Figure 3A all four leads are abnormal, but the diagnostic elements, so far as acute occlusion is concerned, are hidden by the bundle branch block. However, Lead 4 is quite suggestive of anterior infarct. In two days (Fig 3B) this was clear in both standard and chest leads.

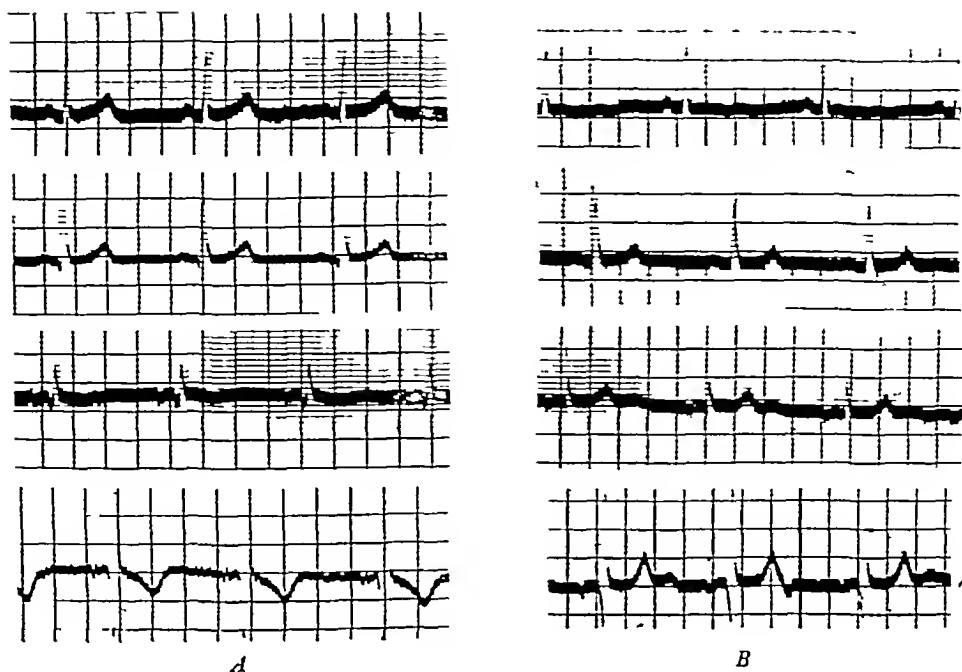

Figure 7 Case 4

A One year before occlusion

B Twelve hours after occlusion

In the tracings taken three and eight days after the occlusion (Fig 4A and 4B) the standard leads, while suspicious as to Lead I, do not give the clear information of Lead 4, with its persistent abnormalities in S-T and Q phases.

Case 3 A. H., a 55-year-old man, was well until Sep-

tember 11, 1937, on that day while watching a tennis match he felt an oppression in his chest. An electrocardiogram taken shortly afterward was normal. During the next month, however, he had more chest pain on exertion, which was relieved by nitroglycerin. On September 30

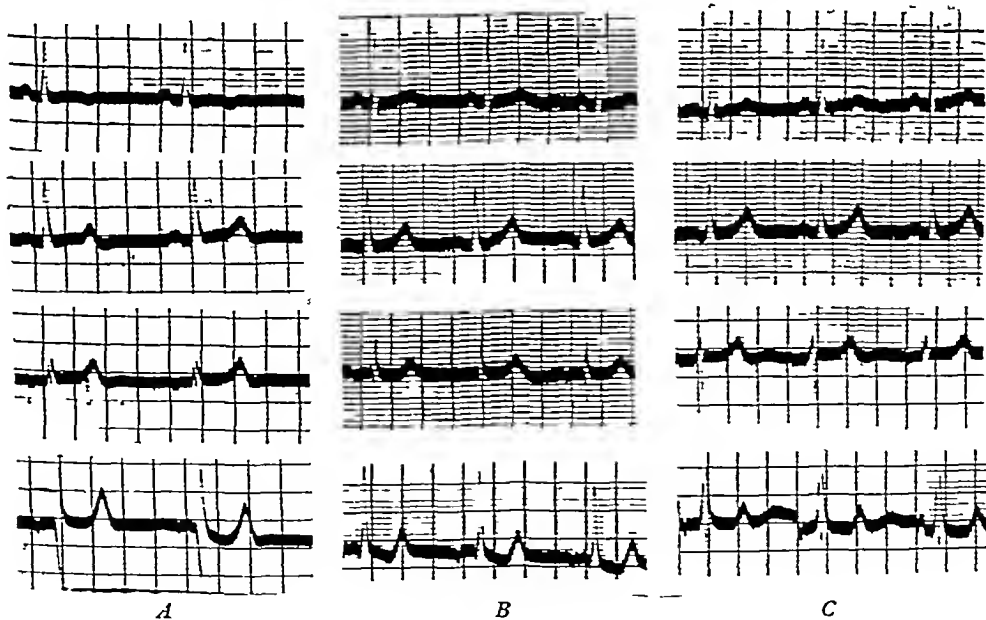

Figure 8 Case 4

A Six days after occlusion

B Twenty days after occlusion the conventional leads having returned to normal

C Five weeks after occlusion

after dinner he had a severe burning pain over the sternum, radiating down both arms. His blood pressure fell from 140/80 to 100/60. His pulse, which was 80 at first, rose to 104 and the temperature to 100.4°F 2 days later.

An electrocardiogram taken September 12, 1937 (Fig 5), shows no abnormality in any of the complexes except a very slight slurring of the QRS in Lead 2. The tracing taken on October 2 (Fig 6), forty-one hours after the onset of the occlusion, shows a suspicious elevation of the S-T segment in Lead 1, but an entirely characteristic picture of anterior occlusion in Lead 4. It should be noted that Lead 4 was taken with the more recent technic, and therefore has a reversed polarity as compared with the others here shown.

Case 4 J. K., a 36-year-old man, entered the hospital on April 7, 1937, complaining of dyspnea and precordial pressure on exertion, following a severe chest pain 2 years previously, associated with pain in the left arm. On the day before admission he was awakened by a severe chest pain, with radiation into the left arm, which lasted for 1 hour. His temperature was 100°F. The white-cell count was 8800, the blood pressure was 135/80, and the heart sounds were of good quality. A 7-foot heart plate showed the heart to be at the upper limits of normal size. A blood Hinton test was negative. After 4 weeks the patient was discharged to his home, where he was comfortable except for precordial pain on exertion. On June 10, 1937, he started to seek employment, but had to give up because of chest pain. After that time he had frequent, severe chest pains, and on June 13, 1937, he came to the Emergency Ward with the most severe pain he had yet experienced, with radiation into the left arm and the jaw. The heart sounds were distant, the blood pressure was 110/90,

and the white-cell count was 10,000. He died suddenly the next morning.

Postmortem showed that the heart weighed 325 gm. Along the lower half of the interventricular septum and somewhat involving the anterior portion of the left ventricle at the apex, the myocardium and endocardium were dull steel-blue in color and somewhat thin. The main coronaries showed marked yellowish atheromas. Three millimeters beyond the descending branch of the left coronary there was an old occlusion. Five millimeters beyond the origin of the circumflex branch of the left coronary the artery was almost occluded, and 1 cm. farther along the closure was complete. The right main coronary artery showed recent occlusion.

Figure 7A cannot be considered diagnostic of coronary occlusion, in spite of the findings at autopsy indicating that an infarction of the apical and septal region of the heart had taken place one year before. Twelve hours after the second occlusion (Fig 7B) Lead 1 was very suspicious, especially so when compared with an electrocardiogram taken on March 16. Moreover, the slightly inverted T wave in Lead 3 of the previous tracing had become upright, conforming to the pattern of anterior occlusion. Lead 4, however, showed the most marked change in the T wave direction. Figures 8A, 8B and 8C are interesting as showing the return of the standard leads to normal, except for a slight left-axis deviation and a persistent abnormality in Lead 4. In this case a standard three lead electrocardiogram taken only 20 days after an acute coronary thrombosis, and 2 years after another, was within normal limits, and the diagnostic features were confined to the direct chest lead.

THE SIGNIFICANCE OF THE WEAKLY POSITIVE ASCHHEIM-ZONDEK TEST

BENJAMIN TENNEY, JR., M.D.,* AND FREDERIC PARKER, JR., M.D.†

BOSTON

IN THE routine Aschheim-Zondek tests for pregnancy as performed at the Boston City Hospital, the reports fall into three groups: positive, weakly positive, and negative. All tests are read by examining, microscopically, stained sections of the rats' ovaries. In the definitely positive and negative tests there is no doubt about the interpretation in our minds or in those of the patients' physicians. In the weakly positive cases, however, there is often uncertainty in the minds of all concerned, and we are asked whether the patient is pregnant. In order to clear up this confusion, we have followed through to a definite diagnosis 60 cases in which the report was weakly positive. In all the cases of miscarriage such a diagnosis was evident, either from gross observation or from microscopic sections of placental tissue. In all the other cases the diagnosis was confirmed by microscopic sections. The cases were without exception taken from the gynecological and obstetrical service of the Boston City Hospital. Many of them were observed and cared for by one (B. T.) of us.

In a positive test, we must remember, the immature female rat's ovaries respond either to two separate hormones or to one pituitary hormone in two different ways. The present weight of opinion is that there is a pituitary follicle-stimulating hormone as well as a pituitary luteinizing hormone. The first causes the growth of the ovarian follicles, and must be present before the luteinizing hormone can change the ripe follicle into a corpus luteum. In addition to these pituitary hormones there is the prolactin which is found in pregnancy urine. It also causes the formation of corpora lutea in the immature rat ovary. This pregnancy-urine prolactin is thought to be of placental origin, although it is so similar to the luteinizing hormone of the pituitary that its separate entity is not a certainty. It is this prolactin that gives the positive Aschheim-Zondek test.

In the first two or three weeks following conception, injection of urine gives only a follicle-stimulating effect in immature rats. In other words, there is follicle growth without formation of corpora lutea. This is due either to the presence of the pituitary hormone or to the follicle-stimulating effect of a very small amount of pregnancy prolactin.

While this result cannot be read as a positive Aschheim-Zondek test, it is extremely suggestive of pregnancy if the patient is only a few days past her period. Following this early phase, enough pregnancy prolactin is present in the urine to produce definite corpora lutea in the immature rat. There is an intermediate stage between the two extremes in which follicle growth is stimulated and there is luteinization of the follicle cells without the formation of a distinct corpus luteum. This is the weakly positive test. The same cycle is reversed when a fetus dies. Such a pregnancy may first have given a definitely positive test. As the trophoblast of the placenta degenerates the hormone diminishes, resulting in a weakly positive test. Thereafter the minute amount of prolactin gives only a follicle-stimulating effect, and finally the test becomes negative.

It can thus be seen that in very early pregnancy a weakly positive test is the normal finding. In a woman with a twenty-eight-day menstrual cycle, the Aschheim-Zondek test when made six weeks from her last regular period should be definitely positive in a healthy pregnancy. The cases considered in this paper are those of women who were more than two weeks overdue and so would have been expected to have had positive tests.

In several cases that have shown a weakly positive test we have concentrated the urine and obtained a definitely positive result. These turned out to be abnormal pregnancies, however. Concentration is therefore of no value in this type of work. If a patient does not have enough prolactin to give a positive test with whole-urine injection, she has either a very early or a pathologic pregnancy.

Table 1 Final Diagnosis in 60 Cases Showing a Weakly Positive Aschheim Zondek Test

DIAGNOSES	NO. OF CASES
Miscarriage	38
Tubal pregnancy	12
Dead fetus	5
Hyperplasia of endometrium	2
Tubo-ovarian mass	2
Hydatid mole	1
Normal pregnancy	0

The relative occurrence rates of miscarriage and of tubal pregnancy in Table 1 are of no significance, because the usual miscarriage prevents no diagnostic difficulty and does not receive an Aschheim-Zondek test.

One fact stands out prominently in our final statistics: no patient with a weakly positive test had

* Junior visiting surgeon, Department of Obstetrics and Gynecology, Boston City Hospital; assistant obstetrician, Massachusetts General Hospital.
† Associate professor of pathology, Harvard Medical School; director, City Institute of Pathology, Boston City Hospital.

a normal pregnancy. This in itself is of value in the treatment of threatened miscarriage. As such cases are apt to occur in the second and third months of pregnancy, a positive test at this time gives a good prognosis, while a weakly positive test gives a practically hopeless one.

From the miscarriages recorded here, and the great number that might be added were they tested, it is evident that with a weakly positive test the first probability is that one is dealing with a blighted ovum, or an unhealthy pregnancy which will terminate in a miscarriage. We see many patients with staining in the second and third months of pregnancy. We feel that in these cases an Aschheim-Zondek test is of prognostic value.

The next most important finding is the relatively large number of cases with weakly positive tests that proved to be tubal pregnancies. One would expect this when one considers the lesion of tubal pregnancy. The ovum is implanted in an abnormal and unhealthy environment, and its normal growth is impaired. Few tubal pregnancies continue very long without damage to the ovum, which soon loses its vitality, the physiologic secretion of the cells accordingly becoming less. Fortunately, in most cases local symptoms which suggest the diagnosis are present. While on the laws of chance a weakly positive test points to a poor intrauterine pregnancy, it can be seen from this series that tubal pregnancy is of sufficient frequency to require that it be carefully ruled out. As we all know, one of the dangers of tubal pregnancy is that the condition is so rare that the diagnosis is unlikely to enter the physician's mind. This test definitely suggests it as a possibility.

The 5 cases with dead fetuses could strictly speaking be classed as miscarriages. Four of these were in the last trimester. The test is of additional evidence in such cases, but is probably unnecessary for diagnostic purposes.

The weakly positive tests in the 4 nonpregnant cases, 2 of hyperplasia of the endometrium and 2 of tubo-ovarian abscess, are difficult to explain. We do know that estrogenic hormones are the essential cause of endometrial hyperplasia. This may

be the result of an excess of the follicle-stimulating hormone of the pituitary. Furthermore, in the cases of tubo-ovarian masses where the ovary had been destroyed there may have been some castration effect on the pituitary. These 4 cases therefore suggest that the positive reactions were due to the presence of gonadotropic hormones of the pituitary.

The single case of hydatid mole is of interest in that the weakly positive test fits in with our findings in 2 cases of early chorioepithelioma. In these we found less hormone than is encountered in normal early pregnancy. This shows that while an extremely high hormone content of the urine is present in well-advanced cases of hydatid mole and chorioepithelioma, it is not present in the early stages. For the sake of the patient the diagnosis should be made, if possible, when the hormone is present in only small amounts.

SUMMARY AND CONCLUSIONS

Sixty cases that showed a weakly positive Aschheim-Zondek test for pregnancy have been followed to a definite diagnosis. None were included in which the last period was less than two weeks overdue. Cases up to eight months' pregnancy were included. In this series the majority of patients miscarried. In a relatively large number tubal pregnancy was found at operation. Four cases gave diagnoses other than pregnancy, and thus suggested the presence of abnormal amounts of pituitary hormones. No patient had a normal pregnancy.

From this it seems likely that after the first few weeks of pregnancy a weakly positive Aschheim-Zondek test indicates some abnormality. A miscarriage following an unhealthy pregnancy is the commonest sequela, and a weakly positive test with a clinical diagnosis of threatened miscarriage indicates a poor prognosis. Tubal pregnancy must always be carefully considered as a diagnostic possibility in this type of test.

A weakly positive Aschheim-Zondek test may be of as much value as a positive or negative one.

NEUROLOGIC MANIFESTATIONS OF SUBACUTE BACTERIAL ENDOCARDITIS

CHARLES M. KRINSKY, M.D.,* AND H. HOUSTON MERRITT, M.D.†

BOSTON

THE central nervous system is frequently involved in the course of many well-known diseases in which the primary pathologic process is far removed from the brain. One such disease, subacute bacterial endocarditis, has a high incidence of neurological symptoms, and since these symptoms are not infrequently the first to occur, they may lead to the impression that the primary lesion is in the nervous system, and hinder rather than aid in arriving at the correct diagnosis. It is the purpose of this paper, first, to present 3 cases which gave us considerable difficulty in diagnosis, and secondly, to emphasize the significance of central-nervous-system manifestations in the early recognition of subacute bacterial endocarditis, as determined by an analysis of 100 proved cases admitted to the Boston City Hospital in the last twelve years.

Thayer¹ states in his monograph on bacterial endocarditis that occlusion of the larger cerebral vessels, or, more rarely, rupture of mycotic aneurysms with subsequent hemiplegia, is distressingly common. The former was present in 31 per cent of his 145 cases. Klemmer² reported a series of 6 cases which presented multiple neurological findings. Symptoms referable to the nervous system were observed in 25 per cent of DeJong's³ cases. Blumer⁴ found that headache was the commonest symptom, and that this was closely followed by vertigo, tinnitus, insomnia, irritability, extreme nervousness, delirium, somnolence, coma and convulsions, cerebral embolism was the cause of death in 44 out of 193 cases. Osler⁵ reported 3 deaths from this cause out of a series of 10 cases.

CASE REPORTS

Case 1. A 27-year-old white man was admitted complaining of severe headache, blurring of vision, deafness in the left ear and muscular weakness on the left side. Three months before admission the patient had headache and malaise, accompanied by fever. Transient attacks of slurred speech were noted. These episodes were followed in short order by a siege of migratory arthritis, which periodically confined him to bed. He had had a cough productive of mucus for several months preceding admission, and had lost 20 lb. during his illness. Ten days before admission the right-sided headache became more severe, followed by drowsiness, blurring of vision, numbness of the left side and difficulty in using the left arm and leg.

‡Assistant professor of neurology, Harvard Medical School; assistant visiting neurologist, Boston City Hospital.

The past history was noncontributory except for an attack of acute rheumatic fever at the age of 14.

On physical examination the patient did not appear acutely ill. The temperature was 99°F, the pulse 100, and the respirations 20. The heart was not enlarged to percussion, and the rate and rhythm were normal. The second mitral sound was split, but no murmurs were heard. The blood pressure was 140/75. The nasal margins of the optic disks were obscured, and in the macular region of the left fundus there was a dull red area a few millimeters in diameter. No definite weakness on the left side could be demonstrated, but there were hypalgesia and hypesthesia of the skin on the left side. The deep reflexes were active and equal, and the plantar responses were normal. The abdominal and cremasteric reflexes were absent. There was difficulty in recalling words and dates and a definite tardiness of responses, but no actual aphasia.

Examination of the urine showed a very slight trace of albumin, from 4 to 6 white blood cells per high power field and an occasional granular cast. The hemoglobin was 73 per cent (Sahli), the red blood-cell count was 3,950,000 and the white-cell count 12,000. An x-ray of the chest and skull and an electrocardiogram were normal. The spinal fluid was under an initial pressure of 140 mm. of water. The fluid was clear and slightly yellow, and contained 200 cells per cu. mm. The globulin test was positive, the protein content was 84 mg., the sugar content 48 mg. and the chloride content 693 mg. per cent. The colloidal gold and Wassermann tests were negative.

During the first weeks stay in the hospital there was no particular change in the patient's condition. The temperature remained normal. Re-examination after transfer to the neurological service 1 week after admission showed findings similar to those on admission, except that the heart seemed to be enlarged. The first sound at the apex was muffled, and a soft, systolic, non-transmitted murmur was heard in that area. The second pulmonic sound was accentuated. A small, blue-black, pea-sized and tender subcutaneous nodule was present in the left trochanter region. The patient complained of severe right-sided headache, accentuated on motion of the head. Marked tenderness to percussion was present in the right temporoparietal region. He was unable to read newspaper print at a distance of 35 cm. The margins of the optic disks were blurred and the nerve head appeared to be swollen. There was a slight paresis of the left external rectus muscle. The visual fields were normal. The weakness of the left side which the patient complained of on admission had developed into a definite left hemiparesis, with hemihypesthesia, atopognosis and astereognosis on the same side. A mixed type of aphasia involving both sensory and motor components was evident. The patient was originally left-handed but had been taught to write with his right hand. The deep reflexes were slightly more active on the left.

Re-examination of the spinal fluid at this time showed that it was under a pressure of 160 mm. of water. The fluid was clear and colorless and contained 48 cells per cu. mm. The globulin (Pandy) test was positive. The

protein content was 42 mg, sugar 53 mg and chlorides 730 mg per cent. Colloidal gold and Wassermann tests were again negative.

The difficulty in speaking became progressively worse, and the cardiac signs became more evident. Three weeks after admission there were definite physical signs of mitral and aortic valvular disease. The temperature was now of a picket fence type, ranging between 100 and 103°F, with a corresponding tachycardia. Petechiae appeared in the left conjunctival sac and in the skin of the right wrist and abdomen. Blood culture, taken a few days before the appearance of the petechiae, was positive for *Streptococcus viridans*. The hemoglobin dropped from 72 to 48 per cent (Sahli), and the erythrocyte count from 3,950,000 to 2,770,000. The patient died 8 weeks after admission. Permission for an autopsy was refused.

The diagnosis was made difficult in this case by several factors. First, the development of the hemiparesis and aphasia was apparently of slow evolution, suggesting the expansion of a neoplasm. The changes that developed in the appearance of the optic nerve supported this diagnosis. Secondly, the temperature did not become elevated until a week after admission. Thirdly, sufficient attention was not paid to the history of the old rheumatic fever and the more recent "arthritis." Finally, the cardiac signs were not diagnostic on admission, and petechiae were not seen until almost three weeks afterward. The diagnosis was established by blood culture when the cardiac signs became evident.

Case 2 A 34 year-old, colored man was admitted with a history of a sudden onset of right hemiplegia and speech disturbance. A week before admission, while drinking a glass of soda water, the patient suddenly began to perspire profusely, felt faint and 'shook violently.' He thought he was going to die, and was aware that he could not speak or move the right side of his body. He was carried home, and was brought to the hospital 1 week later because there was no improvement.

One year before admission the patient suffered from occasional dizzy spells and was treated for high blood pressure. A few months later his eyes began to pain and burn, and he was unable to read fine print. At the same time, vague aches and pains were present in his joints and muscles. Night sweats were frequent, and because of loss of weight, general malaise and lassitude it became necessary for him to stop working.

When 14 years old he had had severe joint pains, with episodes of chills and fever lasting several weeks. Other wise the past history was noncontributory.

Physical examination revealed a well-developed and well-nourished man. The temperature was 102°F, the pulse 98 and the respirations 22. The patient was conscious and co-operative, but appeared confused and disoriented and had difficulty in speaking. The heart was enlarged on the left. The rate, rhythm and quality of heart sounds were normal. Presystolic and systolic murmurs were heard at the apex. The blood pressure was 136/100. There was no evidence of cardiac decompensation. There were a complete right hemiparesis and a mixed type of aphasia, with both motor and sensory components. The deep tendon reflexes were exaggerated, being more active on the right. Ankle clonus was elicited on the right. The abdominal and cremasteric reflexes were absent but

no pathologic reflexes were obtained. The gait showed shuffling of the right foot and staggering toward the right.

Examination of the urine on numerous occasions yielded a slight trace of albumin and a few hyaline casts. Blood studies showed a hemoglobin of 73 per cent (Sahli), the erythrocyte count averaged 3,750,000 and the white-cell count was 18,000. A blood Hinton test was negative. The spinal fluid was under an initial pressure of 250 mm of water. The fluid was clear and colorless and contained 38 lymphocytes per cu mm. The globulin test was negative and the protein content was 36 mg per cent. Colloidal gold and Wassermann tests were negative. A second examination of the cerebrospinal fluid was made several days later, and the findings were the same as on previous examination except that the pressure was 170 mm. Blood cultures were positive for *Streptococcus viridans*.

There was no marked change in the patient's condition during his 3 weeks' stay in the hospital. There was intermittent fever, a few petechiae were observed in the right conjunctiva and fundus 5 days after admission, and the spleen became palpable. The patient was transferred to a state institution, where he died 4 months later. No autopsy was performed.

Because of experience with the preceding case, the diagnosis in this one was made promptly after admission to the hospital. The past history of rheumatic fever, the acuteness of the onset of symptoms and the localization of signs, reinforced by a positive blood culture for *Streptococcus viridans*, left no doubt as to the diagnosis. Syphilitic endarteritis was excluded by the negative serological tests on both the blood and spinal fluid.

Case 3 A 45 year-old, colored man was admitted complaining of double vision and generalized weakness following the extraction of a tooth. He was confused, disoriented, and hallucinated in the visual and auditory spheres.

The patient had enjoyed good health until 4 days before admission, when a few hours after the extraction of an abscessed tooth he felt generalized weakness. Three days later he was unable to walk, falling on two occasions and injuring his right shoulder. Difficulty in vision appeared 36 hours after the initial weakness, and grew steadily worse necessitating admission to the hospital.

In the past history it was noted that the patient had had a chancre of the penis 15 years before and had received some treatment. He suffered from convulsions until 10 years of age. No history of rheumatic fever or joint pains could be obtained.

Physical examination revealed a well-developed and well-nourished man who was excited, overtalkative and confused, with alternating periods of rational behavior. At times he sang, tried to get out of bed and struggled at the restraints. He realized that he was in a hospital, but did not know in which one. The temperature was 100°F, the pulse 96, and the respirations 28. The pupils were fixed to light and accommodation. A divergent strabismus was present. The eyes were able to follow a finger on downward gaze and to a very slight extent on upward gaze. No motion was present in any other direction. There was ptosis of both upper lids, more marked on the left, with flattening of the left nasolabial fold. The fundi were negative. The heart was enlarged on the left and right. There was a loud aortic systolic murmur which was transmitted upward to the neck, and a diastolic murmur which was heard best to the left of the midline. A double mur-

mur was heard over the mitral area. The blood pressure was 118/74. The speech was nasal in character, and the masseter muscles were weak. There was a generalized weakness of all muscles, but the greatest involvement was present in the lower extremities. The right deep-tendon reflexes were slightly more active than on the left side. There were bilateral Babinskis.

Examination of the urine showed a slight trace of albumin, occasional clumps of white blood cells, and rare hyalin and granular casts. Blood examination showed a hemoglobin of 84 per cent (Sahli), a red-blood-cell count of 4,510,000, and a white-cell count between 6650 and 17,500. A blood Hinton reaction was positive, and a blood culture was negative. An x-ray of the chest showed fluid at the left base. The spinal fluid was under an initial pressure of 180 mm. of water. The fluid was clear and colorless and contained 15 cells per cu mm. The protein content was 30 mg. per cent, and colloidal gold and Wassermann reactions were negative.

The temperature, which had ranged between 99 and 101°F on admission, rapidly became septic in type, varying between 100 and 105°F. The pulse was 120 and the respirations 30. No petechiae were seen. Dullness, increased breath sounds and moist rales were present at both bases posteriorly. Another blood culture was negative. The pupillary reactions, at first absent, returned later, otherwise there was little change in the neurologic status. During the last week of illness frequent bouts of profuse sweating accompanied by psychomotor hyperactivity occurred. Between these episodes the patient appeared rational and co-operative. He died suddenly 4 weeks after admission.

The necropsy was performed 15 hours post mortem by Dr. D. R. Wier of the Mallory Institute of Pathology. The heart weighed 500 gm. There was marked thickening and stenosis of the mitral and aortic valves. The chordae tendineae were thickened and shortened. An adherent, firm, mural thrombus extended through the mitral valve, and adhered to the adjoining endocardium of the left ventricle. On the surface of this thrombus was a small amount of formed blood clot. The convolutions of the brain were narrowed and the sulci widened. On cut section, sharply demarcated areas of necrosis were present in the right substantia nigra (0.5 by 0.2 cm.) and in the posterior part of the right quadrangular lobe of the cerebellum (2.7 by 0.8 cm.), the latter was yellow red and confined to the cortical ribbon. Similar infarcts were present in the anterior part of the vermis and in the pons.

Microscopic examination of the heart showed marked degeneration of the muscle bundles. The valves were thickened by dense hyalin tissue and infiltrated by a few lymphocytes and mononuclear cells. No bacteria were seen in sections stained by the MacCallum-Goodpasture method. Microscopic examination of the brain showed the following: The right substantia nigra disclosed an area in which the normal architecture was completely destroyed and which was diffusely infiltrated by fat-laden macrophages. At the boundary of the lesion were a large number of pigment-bearing macrophages. Similar areas were seen in the left substantia nigra and in the pons. An older lesion made up of many fatty macrophages interlaced by glial cells was present in the pons. The cerebellar sections revealed an area of softening 1.6 by 9 mm. The cortical ribbon was completely broken down and replaced by fat-laden macrophages. The supporting white matter showed ischemic necrosis. This lesion was bordered by several smaller ones in which glial proliferation could be seen. The medulla oblongata was normal.

This patient presented a diagnostic problem which was not solved even at the time of death. The difficulty in this case arose from the rapidity of evolution, the multiplicity of signs of involvement of the brain stem, the history of a chancre and a positive blood Hinton reaction, and negative blood cultures. Diagnoses of epidemic encephalitis and of syphilitic meningoencephalitis were entertained. Neither could be substantiated. The bizarre nature of the clinical picture did not suggest subacute bacterial endocarditis, but recapitulation brings out many similarities between this and the previous cases. The onset of symptoms coming so abruptly after the extraction of an abscessed tooth was of great significance. Although this case was not proved by the requisite criteria, it has been included because of its startling similarity.

STATISTICAL DATA

The total admissions to the Boston City Hospital between the years 1924 and 1937 numbered 385,397. In this period the diagnosis of subacute bacterial endocarditis was made in 267 cases but on critical analysis it could be thoroughly substantiated by generally accepted criteria in only 100 cases. This diagnosis was considered established beyond any reasonable doubt if a positive blood culture of *Streptococcus viridans* was obtained, or if this organism had been demonstrated in the fresh valvular vegetations on postmortem examination. These are essentially the criteria suggested by Davis and Weiss.⁶ They were the basis for the diagnosis in the 100 cases which constitute this series. The average age was 31.8 years, and the ratio of males to females was 57:43.

Thirty-one per cent of the cases were admitted to the hospital with one or more neurologic manifestations. In most of the cases these led to erroneous diagnoses, such as Schilder's disease, anterior poliomyelitis, cardiac psychosis, scurvy, polyneuritis, mycotic cerebral aneurysm with rupture, cerebral hemorrhage, encephalitis lethargica, central-nervous-system syphilis, brain tumor and tuberculoma. In most cases the correct diagnosis was made late in the course of the disease. Seven cases were diagnosed at necropsy examination and clinically were thought not to be instances of subacute bacterial endocarditis.

Definite signs of involvement of the central nervous system were present in 31 per cent of the patients on admission. In 20 per cent the symptoms and signs were so predominantly neurologic that the primary lesion was thought to be in the central nervous system.

The frequency of the various symptoms and signs referable to the central nervous system is shown in Table 1. It will be seen that headache, speech

difficulty, vomiting, drowsiness, coma and dizziness were the most frequent symptoms, occurring in from 15 to 24 per cent of the cases. Confusion, delirium, visual symptoms, restlessness, nervousness, irritability, irrationality, convulsions and emo-

one side to absence of deep reflexes. Seven per cent showed a positive Kernig sign. Subarachnoid hemorrhages were found in 2 patients on admission, and an intracerebral hemorrhage was present in 6.

Table 1 *Incidence of Neurologic Symptoms and Signs in 100 Proved Cases of Subacute Bacterial Endocarditis*

Symptoms	PERCENTAGE OF CASES	Signs	PERCENTAGE OF CASES
Headache	24	Hemiplegia or hemiparesis	31
Speech difficulty	19	Cranial nerve palsies	25
Vomiting	18	Reflex changes	22
Dizziness	17	Hemorrhages in ocular fundi	22
Coma	17	Choked disks	8
Drowsiness	15	Positive Kernig	7
Confusion	10	Clonus	5
Visual difficulty	10	Positive Babinski	4
Delirium	6	Tremors in extremities	2
Restlessness			
Irritability			
Irrationality			
Convulsions	5		
Nervousness			
Emotional disturbance	2		
Hiccough	1		
Hearing difficulty			

tional disturbances were the next most frequent symptoms, being reported in from 5 to 10 per cent. Two cases of intractable hiccough occurred, and 1 patient complained of loss of hearing. These statistics are in agreement with those of Blumer,⁴ previously cited.

Hemiplegia or hemiparesis and cranial-nerve paralysis were the most frequent neurologic signs, occurring in 31 and 25 per cent, respectively. Many of the cases of cranial-nerve paralysis should be excluded because they consisted of facial paralysis accompanying a hemiplegia. In a few instances there was a ptosis or a hypoglossal paralysis. Choked disks were observed in 8 patients, and hemorrhages in the fundi in 22. Sixteen cases presented hemiplegia on admission. The reflex changes varied from an exaggeration of reflexes on

SUMMARY AND CONCLUSIONS

Two certain and 1 unproved case of subacute bacterial endocarditis with neurologic signs, which offered considerable diagnostic difficulty, are reported.

Thirty-one per cent of the 100 patients with subacute bacterial endocarditis admitted to the Boston City Hospital between 1924 and 1936 showed one or more neurologic manifestations on admission. In 20 per cent the symptoms and signs were so predominantly neurologic that the primary lesion was thought to be in the central nervous system.

Subacute bacterial endocarditis should be kept in mind as a diagnostic possibility when a young adult is admitted to the hospital complaining of drowsiness, severe headache, double vision, impairment of speech or sudden loss of consciousness, particularly when he shows cranial-nerve palsies or a hemiplegia. These neurologic manifestations may be the earliest evidence of the existence of subacute bacterial endocarditis. Careful examination of the heart and repeated blood cultures will prevent errors in diagnosis.

The authors acknowledge the aid given by Miss Ruth T. Church in the compilation of the data.

TRACY B. MALLORY, M.D., *Editor*

CASE 24131

PRESENTATION OF CASE

A forty-seven-year-old Italian fruit dealer entered the hospital with the complaint of chronic cough.

As a young man he had malaria over a period of about six years, and during that time he first began to cough. He coughed daily for the thirty years before entry. At the time of entry he had spells of coughing when he rose in the morning, after his lunch and supper and at night. He raised a total of more than a cupful of thick, yellow non-odorous sputum daily. He thought that the sputum had increased in amount during the five years before entry. He had occasional night sweats but no chest pain, hemoptysis, continued fever or other cardiorespiratory symptoms, except slight dyspnea on mild exertion. He thought that at about the age of five he had empyema in the right chest which was operated on and drained for a month.

Twenty years before entry he had influenza, "double pneumonia" and typhoid fever. He did not remember what childhood diseases he had had. He had had frequent colds and occasional epistaxis after blowing his nose. He had not lost any weight. His past history was otherwise negative, and his family history was not contributory.

Physical examination revealed a well-developed and nourished Italian appearing to be in excellent health. There was an operative scar 1 cm above the right nipple. His heart was negative, and the blood pressure was 140 systolic, 80 diastolic. The lungs showed no dullness to percussion. At the right base and in the lower part of the right axilla many coarse moist rales could be heard, without change in the breath sounds. However, in the left axilla between the left nipple and the left posterior axillary line similar moist rales could be heard, without other signs. The extreme bases of the lungs were clear. There was moderate clubbing of the fingers.

The temperature was 98°F., the pulse 85. The respirations were 20.

The urine showed the slightest possible trace of albumin. The blood showed a red-cell count of 4,770,000 with 85 per cent hemoglobin, and a white-cell count of 16,700 with 78 per cent polymorphonuclears. The sputum contained numerous pus cells

and a few diplococci, but no tubercle bacilli. The nonprotein nitrogen of the blood serum was 20 mg per cent, and a blood Hinton test was negative. An electrocardiogram showed slight left-axis deviation.

An x-ray of the chest revealed a sharply defined rounded area of density completely occupying the region of the right middle lobe. The left lung and the upper and lower lobes on the right were clear. The heart shadow was a little prominent in the region of the left ventricle. There were no mediastinal masses.

On the fourth day an operation was performed.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON. Here is the round mass that was described occupying the entire area of the middle lobe. The shadow looks larger and rounder than the middle lobe would ordinarily appear but it does not cross the interlobar fissures. It is apparently confined to the middle lobe. He has thickened pleura over the right apex and along the upper axillary line. His right diaphragm moved well except at its anterior portion. The diaphragm is relatively low on both sides. In this dense shadow you can see two or three areas of diminished density with horizontal lower borders which suggest small cavities with fluid levels. This is the upper margin of the mass, and if these shadows are cavities, then the wall of the mass is quite thin. Apparently it is a thin-walled fluid-containing mass. There is no evidence of metastatic cancer or enlarged nodes.

DIFFERENTIAL DIAGNOSIS

DR. JOHN W. CASS. The story of a forty-seven-year-old man with a cough of thirty years' duration means that the history may well be incomplete. It may have been difficult for the man to remember the onset of his illness, and incidents such as foreign-body inhalation or acute respiratory infection may have been forgotten. As a youngster over a period of six years he was supposed to have had malaria, and during that period he noticed cough. This was the first illness that he remembered much about. It may not be the true onset of the cough. However, he does remember that for a number of years, apparently thirty, the raising of sputum associated with this cough occurred chiefly in the morning, after meals or often at night, which means there was a cavity or several small cavities, the drainage of which was aided by intra-abdominal pressure changes. The sputum was thick and nonodorous. There is nothing particularly characteristic about that, though it indicates that the usual mouth spirochetes had not complicated the infection. He thought the spu-

tum had increased in amount. That is very indefinite and of no significance that I can see. He had occasional night sweats—an indication of infection—but no chest pain and no hemoptysis. The fact that he had no continued fever means, I presume, that the infection was fairly adequately drained. There were no cardiorespiratory symptoms except dyspnea, so the process was probably not extensive, and did not cut down the vital capacity or add any burden to the circulatory system. He had had empyema at the age of five, which drained for a month. This is important because an empyema can last this long, and if the raising of sputum and cough did not occur until many years after the original empyema, it is possible that a bronchial fistula developed many years after the original empyema.

The influenza and "double pneumonia" twenty years before entry are probably of no significance, since the underlying chronic lung infection may have made him more susceptible to other chest infections. He had had frequent colds but lost no weight, which means that the disease had been handled fairly adequately and that he had not suffered any great impairment of health. From the history there are many diagnoses suggested, namely bronchiectasis, tuberculosis, abscess, empyema with a bronchial fistula, unusual infection, such as is caused by yeasts or fungi, or even possibly a benign tumor.

On physical examination it was again mentioned that the patient was well-developed and nourished. He appeared in excellent health. There was an operative scar on the right side, evidently the area of drainage of the empyema. The blood pressure was 140 systolic, 60 diastolic, with a normal heart, which again means that the disease had not handicapped his circulatory system. The lungs showed no dullness, which is surprising, you would expect dullness from a localized area of disease that was capable of producing a cup of sputum.

"At the right base and in the lower part of the right axilla many coarse moist rales could be heard, without change in the breath sounds." So there is disease by physical examination on the right side, but on the left side there were similar rales. This is confusing. One would like to believe one was dealing with a more local process.

Clubbing of the fingers is usually indicative of congenital heart disease, which is absent in this case, or a suppurative lung condition. By physical examination we can demonstrate a lung condition, and the findings are more compatible with bronchiectasis than with the others mentioned. I attach no significance to the temperature, pulse and

respirations. He must have had fever from time to time, but with a chronic lung condition with fairly good drainage it is possible to have little or no fever.

The nonprotein nitrogen was normal. He probably had no real chronic nephritis. He perhaps had amyloid disease, which one does have to think of with a process of this duration. There is no Congo red test to help to make this diagnosis. I do not see how it can be made on the basis of the information at hand. The sputum shows nothing definite. No tubercle bacilli were seen and one would think they could be found easily in a process draining as freely as this. The blood Hinton test was negative, there is nothing to suggest a syphilitic process. The electrocardiogram seems to be compatible with the patient's age. The absence of right-axis deviation means that the process caused no great impairment to the pulmonary circulation.

From the laboratory work we cannot rule out any of the mentioned diagnoses. Lipiodol would be a great help in the diagnosis of bronchiectasis. Tuberculosis I think has been ruled out. I do not believe we are dealing with cancer, and we narrow the diagnosis down a bit. The x-ray gives us the first definite localization of this process, localizing it to the right middle lobe, particularly in the lateral film which is so important in middle lobe disease, as pointed out by Dr. Hampton. It does not bear out the finding of disease in the left lung by physical examination and gives us a little more confidence in the belief we are dealing with a fairly localized infectious disease—a chronic suppurative lung condition limited to the right middle lobe. Although a bronchoscopy has not been done, I think benign tumor can be ruled out, because we usually find a good deal of collapse in the middle lobe in this condition. There is no evidence on physical examination to suggest tapping the chest, and probably even nothing on x-ray, although to rule out the diagnosis of empyema with bronchial fistula you would have to tap the chest and probably want to review the physical findings that are given here. I think we can say that the process is probably not an empyema with a bronchial fistula, dating back to the original empyema. Such empyemas are very often associated with a bit of tubing that has been left in, or a piece of bone from a rib end. We have several areas of cavitation demonstrated in the x-ray, so I should be inclined to feel we had ruled out bronchiectasis, tumor, and yeast and fungus infections, and that the differential lies chiefly between empyema and lung abscess. On the basis of the x-ray, I will make a diagnosis of multiple lung abscesses with general suppuration of the right middle lobe.

CLINICAL DISCUSSION

DR. RICHARD H. SWEET I thought before the operation that we probably were dealing with multiple cystic disease of the middle lobe because, first, it seemed to be so closely confined to the one lobe, and secondly, the x-ray appearance was not that of bronchiectasis, and it would be rather unusual to have a bronchiectasis of thirty or forty years' standing without some involvement of other portions of the lung. The interesting thing was that when we exposed the lobe it was not small and contracted as is the usual bronchiectatic lobe but there was a large mass of tissue, and protruding from the surface were round hemispherical masses varying from 2 to 5 cm. in diameter or larger. These seemed to be somewhat fluctuant, like cystic tumors. The lobe was pink and closely adherent to the anterior chest wall, also to the diaphragm anteriorly and to the cardiophrenic angle. It was also intimately adherent to the upper lobe and to a portion of the lower lobe. The large thin-walled cystic tumor which Dr. Hampton described was adherent to the adjacent surface of the upper lobe, and in dissecting the mass free we broke into it. It had a wall no thicker than a sheet of paper. We aspirated many ounces of fluid, which was not thick and purulent, such as one sees in lung abscess, but just turbid and watery, very much like sputum mixed with saliva. We finally took the lobe out, Dr. Mallory will tell us what it looked like.

PREOPERATIVE DIAGNOSIS

Bronchiectasis, right middle lobe

DR. CASS'S DIAGNOSIS

Multiple lung abscesses, right middle lobe

ANATOMICAL DIAGNOSIS

Bronchiectasis, right middle lobe, ? congenital type.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY This is the type of case which immediately brings up questions of definition which are not universally agreed upon. What are the differences between abscesses, bronchiectases and cysts? The distinction between the first two I think we should be able to reach agreement upon in theory, though occasional difficulties may arise in practice. The abscess represents a destructive, necrotizing process in the lung parenchyma. It originates in the alveoli, destroys their walls, results in fusion of many alveoli, spreads peripherally until it erodes the wall of a fair-sized bronchus and then partially drains itself, resulting in a cavity. As the process becomes localized it tends to wall itself off with granulation tissue.

Only occasionally does an epithelial lining grow down from the bronchus to line the cavity. In contrast, bronchiectasis represents dilatation of pre-existing bronchi. Not only are they lined with epithelium but in their walls other bronchial structures such as remnants of cartilage, smooth muscle and elastic tissue are usually easily demonstrable. The pulmonary parenchyma—the alveolar tissue—may be collapsed and atelectatic or scarred and contracted as the result of organizing pneumonitis, but it has not been destroyed. With suitable staining methods it can still be recognized.

In contrast to these two clearly defined pathogenic entities, "cysts" and "cystic disease" represent a conglomeration of unrelated conditions. There are parasitic cysts such as hydatids, and neoplastic cysts such as cystic lymphangiomas. There are fluid-filled, epithelial-lined cysts without bronchial connection, which almost certainly represent developmental abnormalities. Finally, there are air-containing cavities with bronchial connection which may or may not show an epithelial lining. In the latter instance they are difficult or impossible to distinguish from emphysematous bullae, in the former from bronchiectatic cavities. There is a fetal form of bronchiectasis,—undoubtedly a developmental abnormality,—which may persist into adult life, that has often been described as cystic disease. I presume that is what Dr. Sweet has in mind in regard to this case, and I can neither rule it in or out. The bronchiectatic cavities in this specimen were unusually large, thin-walled and superficial. On the other hand I have seen similar pictures in what I believe was acquired bronchiectasis. His history of respiratory infections runs back to childhood. You can interpret them as the etiologic factor in the development of acquired bronchiectasis or as episodes of infection of congenital bronchiectatic cavities, as you will. My choice, I must admit, is for the commoner acquired type.

DR. HAMPTON If the cavities in the lung had no bronchial connection would you not admit the diagnosis of cystic disease?

DR. MALLORY Yes, I should not know what else to call it. But in general, in view of the vagueness of the term, it should be used as rarely as possible.

CASE 24132

PRESENTATION OF CASE

A forty-three-year-old, white, American jeweler entered the hospital with the complaint of difficulty in swallowing.

About eleven months before entry he first noticed that solid foods seemed to stick in his throat. During the next five months this condition gradu-

ally became more severe without pain or other symptoms. At the end of that time the dysphagia increased markedly and was associated with regurgitation. The regurgitated food was occasionally blood streaked. His physician made an x-ray examination and told him that there was some delay in the passage of barium down the esophagus but no definite lesion. He gradually changed to a semisolid diet and for the two months before entry took only liquids. He had no nausea or vomiting or other gastrointestinal symptoms. Three weeks before entry he went to an outside hospital where a barium meal was given and esophagoscopy was done. Following the esophagoscopy he was unable to swallow anything, and this condition persisted up to the time of entry to this hospital. He was kept alive by parenteral fluids. During his illness he had lost about 40 lb in weight and had become very weak and anorexic. He had no other symptoms, and his past and family histories were noncontributory.

Physical examination revealed an emaciated, dehydrated, cachectic man who was unable to swallow even his saliva. There was marked pallor of the skin and mucous membranes. There was soft, diffuse fullness of the lower anterior part of the neck without definite fluctuation. The physical examination was otherwise negative. The blood pressure was 130 systolic, 84 diastolic.

The temperature was 102°F, the pulse 90. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 5,200,000 with 90 per cent hemoglobin, and a white-cell count of 18,600 with 88 per cent polymorphonuclears. The blood Hinton test was negative. The nonprotein nitrogen of the blood serum was 18 mg per cent, the chlorides were equivalent to 102 cc of N/10 sodium chloride, and the protein was 5.3 gm per cent.

On the day following entry an operation was performed for drainage of a retropharyngeal abscess. An incision was made over the clavicle and dissection carried down to the esophagus, where about 120 cc of very foul pus was found in the periesophageal area. A stained smear of the pus showed slender gram-positive bacilli, gram-negative bacilli, and gram-positive cocci in clusters and chains. He continued to run a septic temperature and drained moderate amounts of material from his neck wound. On the fifth day he began to expectorate foul pus, which apparently came from his nasopharynx. A stomach tube had been passed, and he was being given adequate amounts of fluid and nourishment. Early in the morning of the eighth day he bled profusely from his mouth. The bleeding was controlled by setting him up in bed,

but a few hours later he bled profusely again, this time from the wound in his neck. The blood was apparently of venous origin, as it was dark in color and oozed out slowly. The bleeding from the neck occurred twice that day and was controlled by packing of the sinus and by the application of pressure bandages over the shoulder. He was given three transfusions of 500 cc each. Late in the afternoon of the same day he coughed up a little blood and five minutes later suddenly became very dyspneic, he rapidly lost consciousness and died within a few minutes. Just before this final episode his pulse and blood pressure were observed to be normal.

DIFFERENTIAL DIAGNOSIS

DR EDWARD B. BENEDICT. We have to consider all the possibilities of esophageal obstruction in this patient, although most of them seem unlikely. We must first determine whether it is an extrinsic lesion or an intrinsic one. Among the extrinsic lesions is neoplasm of the mediastinum, either primary or secondary. If the lesion is mediastinal, causing these esophageal symptoms, we should have other symptoms such as pressure on the recurrent laryngeal nerve, pressure on sympathetics, causing Horner's syndrome, or pressure on the trachea with deviation and possibly dyspnea. Goiter might produce pressure on the esophagus, and there is swelling of the neck, but that was later proved to be inflammatory, and furthermore, I do not believe that goiter alone could give complete esophageal obstruction. Aneurysm is partially ruled out by the negative Hinton test, and also I cannot conceive of its giving complete obstruction of the esophagus.

Then we come to intrinsic esophageal disease, and the first thing we think of is foreign body. There is no history of such. There is no history of caustic burn. Paralysis of the esophagus is rare and would not give complete obstruction. Diverticulum of the esophagus is unlikely from the history, and would not give complete obstruction. Syphilis of the esophagus is very rare, and the Hinton test is negative. Tuberculosis is very rare. Actinomycosis is extremely rare. Ulcer of the esophagus occurs chiefly at the lower end, whereas this lesion apparently was in the upper portion. Ulcer is also rare and usually gives substernal pain, of which we have no history. Cardiospasm is a fairly common disease of the esophagus. It occurs entirely at the lower end and gives a long history of intermittent symptoms, which we do not have in this case. If it were a benign stenosis from a previous esophagitis or trauma, we ought to have some history of heartburn or trauma, such as is not the case. Also, we have a very ill patient

with complete obstruction, which is unlikely in benign stenosis, furthermore, we have blood-streaked regurgitation, which would be somewhat unlikely

So we come to neoplasm of the esophagus. Benign tumors of the esophagus are very rare, although Jackson has reported myomas, fibromas, myomas, adenomas, angiomas and so forth, but I do not believe they give a picture of this sort. Of the malignant tumors we have sarcoma, which is also very rare. Jackson reported only 7 cases of sarcoma out of 935 malignant tumors of the esophagus. On the law of chance we should be right on a diagnosis of carcinoma because, according to MacMillan at the Massachusetts Eye and Ear Infirmary, that accounts for 40 per cent of all diseases of the esophagus. As one goes over the record it seems as if it were a perfect story for carcinoma of the esophagus—an eleven months' story of difficulty in swallowing, food sticking in his throat, absence of pain, blood-streaked regurgitation, finally restricting himself to liquids, a weight loss of 40 lb., and coming in emaciated, dehydrated and cachectic. It is so typical that it seems too good to be true, but I will make a diagnosis of carcinoma of the esophagus.

Then we have to explain the septic process, the temperature of 102°F., and the white-cell count of 18,000. The serum protein I think was a little low and could go with the starvation. The septic process was undoubtedly due to perforation of the esophagus. Whether it was due to esophagoscopy instrumentation three weeks previously is impossible to say, but it looks suspicious. He was unable to swallow anything immediately afterward. It looks as if they had started up some inflammatory reaction, and possibly a slow perforation developed from that or possibly perforation developed spontaneously. We also have to explain why they could pass a stomach tube if he could not swallow his saliva. I think that is explained by the drainage of the periesophageal process and partial clearing up of the lumen of the esophagus. The final episode of bleeding from the neck seems explainable on the basis of cancer with sepsis infiltrating the periesophageal vessels. I should expect the terminal event to have been a massive hemorrhage, explained on the basis of erosion of a large blood vessel.

I have not asked for any report on the x-rays or esophagoscopies because I suppose they are not available.

DR TRACY B MALLORY: No, they were done at another hospital. Perhaps Dr Sowles can give us some more information.

DR HORACE K SOWLES: I saw this patient on the ward but do not remember the case well. Dr Welch drained the abscess. I shall read his note.

A transverse incision was made about 2.5 cm. above the clavicle with its midpoint overlying the anterior border of the sternomastoid. Dissection was carried down between the sternomastoid and the thyroid gland. The omohyoid muscle was cut. The middle thyroid vein lay above the blunt dissection. The carotid was retracted laterally. A dense layer of fascia was then broken through, and about 120 cc. of very foul pus evacuated from the periesophageal area. A finger could then be introduced into the abscess cavity. It extended behind the esophagus a short distance on either side of the neck, and it extended for a short distance beyond each clavicle, but the abscess cavity was well delimited in the upper mediastinum. Two drains were inserted.

CLINICAL DIAGNOSES

Carcinoma of the esophagus
Retropharyngeal abscess
Secondary hemorrhage
Asphyxiation

DR. BENEDICT'S DIAGNOSES

Carcinoma of the esophagus
Perforation of the esophagus
Periesophageal abscess
Secondary hemorrhage.

ANATOMICAL DIAGNOSES

Carcinoma of stomach, scirrhus, colloid
Perforation of the esophagus
Periesophageal abscess
Pulmonary embolism

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy findings verified each of Dr Benedict's diagnoses up to a certain point, but he did not localize the lesions in quite the right spots. It is true the man had cancer, but he did not have cancer of the esophagus. He had cancer of the stomach. It was a large limit plastica which had extended up and completely occluded the cardiac orifice. It involved a short portion of the esophagus, but there could be no question from the type of the tumor, with its scirrhus growth and its signet-ring cells, that it was primary in the stomach. The esophagus was perforated, but it was perforated through an area that was in all probability previously normal, far above the carcinoma. A large abscess developed about the perforation, and the final hemorrhage came from an erosion of one of the periesophageal veins. The abscess had not extended to any of the major vessels of the neck. The final episode was a massive pulmonary embolus.

PUBLIC-HEALTH ADMINISTRATION IN MASSACHUSETTS

PREVIOUS to 1858 very little attention had been given to the causes and prevention of disease except as physicians had, in connection with practice, given such advice or information as seemed appropriate for patients under treatment. But after the ringing indictment of the people by Lemuel Shattuck in that year, in which he urged sanitary reform because of the "thousands of lives lost which might have been saved, and the tens of thousands of cases of sickness that occur every year which might have been prevented," there was an awakening of interest in preventive medicine. Other public-spirited men united with Shattuck in a campaign to bring about reforms in dealing with disease, with the result that the Massachusetts legis-

lature enacted a law in 1869 creating the first state board of health in this country. Then began the organized battle for better health in this State which has been carried on with increasing success through the succeeding years.

In 1879 the title and functions of the board were changed to include charity and lunacy, and the added burden of these other departments of state administration imposed complicating responsibilities which were not wholly in harmony with purely health matters. As a result, in 1886 the care of the indigent and the care of the insane were transferred to their appropriate administration departments, and the original title of Board of Health was resumed and continued until 1914. In that year certain members of the legislature were informed that plans were being formulated to reorganize the board along lines not wholly devoid of political implications.

This movement was regarded as inimical to improved public-health policies, and a defensive counter maneuver, in the form of a bill designed to preserve these policies and traditions and to keep them free from political influence, was proposed. For this purpose, conferences were arranged by Dr. Enos H. Bigelow, then a member of the legislature, with certain physicians, with the result that a voluntary committee was formed to study the situation and formulate a suitable bill. Fortunately the Hon. David I. Walsh was at the time governor of Massachusetts, he cordially co-operated with the committee and supervised the drafting of the bill. One significant episode in connection with the campaign was the appearance before the Council of the Massachusetts Medical Society of the Governor who proclaimed his approval of the bill and assured the medical profession that he would not "play politics with the public health of Massachusetts." This position of the Governor augmented by the work of Dr. Bigelow in the House of Representatives brought about, in 1914, the passage of the bill creating the Department of Public Health, thus inaugurating a new era in the administration of public health in Massachusetts. This department has never been subjected to political interference.

Throughout these sixty-eight years of public-health administration, eminent physicians have guided the health policies of this Commonwealth. During the years of the Board of Health the executive duties were discharged by two chairmen, Dr. Henry I. Bowditch from 1869 to 1886 and Dr. Henry P. Walcott from 1886 to 1914, assisted by executive secretaries in the personnel of Dr. Henry P. Derby, 1869 to 1874, Dr. Charles F. Folsom, 1874 to 1880, Dr. Samuel Abbott, 1880 to 1904, Dr. Charles Harrington, 1904 to 1908, and Dr. Mark W. Richardson, 1908 to 1914.

With the change to the Department of Public Health, the first step was the selection of a commissioner. On invitation the United States Public Health Service sent two of its officers for consideration, and after conference with Governor Walsh, Dr. Allan J. McLaughlin was appointed to this office. He proved to be an able administrator and served until recalled to federal service in 1918.

Dr. Eugene R. Kelly, deputy under Dr. McLaughlin, was then appointed commissioner. His natural qualities and previous experiences enabled him to carry on the duties of the position with success until his death in 1925, when Dr. George H. Bigelow, deputy under his predecessor, was given charge of the department. Endowed with a brilliant mind and unusual physical vigor, Dr. Bigelow completed programs under way, initiated important changes in administrative detail, and accepted new duties imposed by the legislature, which were carried on with credit. He embraced every opportunity for incursion to new fields of work with enthusiasm and always seemed to adapt himself to meet unaccustomed associations and problems. His powers of adjustment enabled him to succeed in administrative experiments, as for example, the conduct of the state cancer program at Pondville. His term of office extended through eight years. He resigned to accept the directorship of the Massachusetts General Hospital, but he never lost interest in public-health work and used his influence to secure his successor in the person of Dr. Henry D. Chadwick.

By a fortunate coincidence Governor Joseph P. Eli, then in office, knew Dr. Chadwick personally

and was familiar with his great contributions to public health in this State and elsewhere. He approved of Dr. Bigelow's recommendation, and Dr. Chadwick was induced to come back to Massachusetts in 1933 as commissioner.

Dr. Chadwick did not seek the position, the office sought the man. The accomplishments of his four years as commissioner have justified the appointment.

Doctor Chadwick received his medical degree from the Harvard Medical School in 1895 and served a surgical internship at the Boston City Hospital. He practiced medicine in Waltham until 1907 when he was appointed superintendent of the Vermont Sanatorium at Pittsford. In 1909 Dr. Chadwick was invited to direct the construction of a new state sanatorium in Westfield, and was subsequently made superintendent. During the next twenty years, he developed one of the first sanatoriums for tuberculous children in the country, and impressed with the high fatality of pulmonary tuberculosis in children, secured legislative support for a ten-year program for the discovery and control of tuberculosis in children—the first organized state effort in this field, and the most comprehensive plan ever completed.

In 1929 Dr. Chadwick accepted a position in the Detroit City Health Department. He had full charge of the tuberculosis program, and for the first time developed adequate diagnostic and sanatorium facilities for Negroes affected with the disease. To meet the needs for additional hospital facilities he arranged for the subsidizing of beds in private hospitals and the training of medical and nursing personnel to make these beds effective. While in Detroit he was also engaged in the survey of the tuberculosis problems in the cities of Washington and Denver, and advised the official organizations of those cities in the development of their diagnostic and sanatorium programs.

Among his outstanding achievements as commissioner in Massachusetts is an extensive study of the state public-health laws by representatives of various official and voluntary public-health organizations, with the financial assistance of the Commonwealth Fund of New York City. This

study resulted in a comprehensive set of recommendations, many of which have been enacted into law. As a result of one of these the Department of Public Health was authorized in 1937 to contract with one or more metropolitan hospitals for the care and study of a group of not more than twenty-five patients with chronic rheumatism in order to determine the possibilities for relief of the victims of that disease. Another recommendation resulted in the taking over and operation of all municipal syphilis and gonorrhea clinics by the department. As a result of a third recommendation the department has been authorized to set up and maintain special facilities for the transportation of premature infants to certain hospitals for adequate care.

Under a legislative appropriation of 1934 the work of the Pondville Hospital was supplemented by the construction of a ward for twenty-five additional beds and a service and medical building which provides all modern operative facilities for treatment of cancer patients. In 1937 a new unit was added to the Westfield State Sanatorium. This provides fifty beds with complete surgical and radiologic facilities for the treatment of cancer in the western part of the State, and one hundred and forty-four beds for adult tuberculosis.

In 1936 the pneumonia serum program, started with the aid of the Commonwealth Fund, was taken over by the department. This program involved the establishment of some eighty typing and serum-distribution stations in general hospitals throughout the State, in addition to the manufacture of pneumonia serum at the Antitoxin and Vaccine Laboratory at Forest Hills.

With the assistance received under the Social Security Act the department's program in child and maternal hygiene has been greatly expanded, and approximately twelve per cent of the supplementary funds have been used for postgraduate medical education of Massachusetts physicians.

Federal activities under the CWA, WPA, PWA and CCC have greatly increased the department's work and responsibilities in the field of sanitary engineering. This has included a very effective

mosquito control and drainage program on Cape Cod, and the study and approval of plans for a large number of municipal sewage-disposal systems receiving federal aid. Under the guidance of the engineering staff much has been done to reduce pollution of many rivers and streams of the State. At Dr Chadwick's suggestion the sanitary engineering work at all state institutions has been taken over by the department with a substantial saving in expense. Requests from cities and towns for advice and assistance in sanitary problems have doubled in the past four years, and in 1937 a sanitary engineering laboratory was opened in Westfield which provides the same type of service in western Massachusetts which has been previously available in the eastern part of the State.

An example of Dr Chadwick's constructive co-operation with the medical profession is his development of the Services for Crippled Children. Legal responsibility for this work was transferred from the Department of Public Welfare to the Department of Public Health in 1936. With the advice and assistance of the state and district medical societies ten clinics have been established in different areas, at which children are examined only on application of a physician, and hospitalization is recommended only with approval of the local medical society. Physiotherapy, public health nursing and social service are provided through the clinics, acute cases are hospitalized in the local general hospitals, and chronic cases are admitted to the Lakeville State Sanatorium.

In addition to maintaining the efficiency of his department Dr Chadwick has won the respect of the medical profession and local health officials throughout the State. The approval of the Massachusetts Medical Society and the Massachusetts Public Health Association is shown by appropriate resolutions adopted by these bodies at meetings held this year. It is the hope of our people, we believe, that Dr Chadwick be continued in office so that the Commonwealth will still have a public-health service of the highest rank. Such service has been available for over sixty-eight years and should not be interrupted.

CASE HISTORY No 65 PARTIAL SEPARATION
OF THE PLACENTA

Mrs. W., a twenty-nine-year-old primipara, thirty-two weeks pregnant, telephoned at 8.35 a m., December 12, that she was having intermittent and rather severe abdominal pain. A few minutes later her husband telephoned to say that she was bleeding from the vagina and had passed what he estimated to be over a pint of blood.

The family history was unimportant. The patient had had scarlet fever at fifteen but no other illnesses. Catamenia began at seventeen, were regular, every twenty-eight days, and lasted five days without any unusual pain. Her last period was May 4, making the estimated date of confinement February 11.

The patient first consulted her physician on July 8. She was a well-developed and nourished woman. Her heart was not enlarged, there were no murmurs. Her lungs were resonant throughout, and there were no rales. Abdominal examination showed the uterus to be enlarged to a size compatible with the period of amenorrhea. Subsequent visits revealed no complications. The blood pressure averaged about 110 systolic, 70 diastolic, and the urine never showed any evidence of albumin. On July 29 the patient reported a slight brownish discharge after coitus, and on October 10 after an automobile ride, there was a small amount of bleeding.

When seen at home on December 12, the sheet was found to be covered with an area of bright blood about two feet square. An area about two by three feet on the patient's nightgown was also soaked with blood. She had passed clots. There was no other evidence of severe bleeding, but she was "trickling." The uterus was ligneous, and no fetal heart could be heard.

The hospital was immediately notified to set up the operating room for cesarean section, and the patient was transported to the hospital. On arrival she was shaved and catheterized but given no further medication. She and her husband were grouped and cross-grouped with a view to transfusion, but the husband was found to be incom-

patible. A suitable professional donor was located. The patient's temperature was 98.4°F., the pulse 64, regular and of good quality and fair tension. Her blood pressure was 92 systolic, 60 diastolic. An assistant and anesthetist had been summoned and were present on arrival of the patient. A 5 per cent solution of glucose was ready for intravenous medication when needed. An immediate transfusion was not deemed necessary as the patient's general condition was good. No vaginal examination was done. Rectal examination showed a typical primiparous cervix which was not taken up or dilated. In view of the fact that she was a primipara and not in labor, abdominal delivery seemed wisest and safest.

Under nitrous oxide and oxygen and ether anesthesia a low classical cesarean section was done. The membranes were ruptured, followed by a gush of dark blood. A dead male baby, weighing 3 lb., 4 oz., was extracted through the uterine wound. An ampule of posterior-pituitary extract was given intravenously at the time of incision of the uterus, and after delivery of the baby. Examination of the uterus disclosed that the placenta, which was normally seated, was about half separated. The placenta and membranes were delivered complete and intact by suprafundal pressure. This was followed by a considerable amount of blood clot. There was no further bleeding. One ampule of Ergometrine was then given intramuscularly. During the operation 1500 cc of 5 per cent glucose was given intravenously. The patient's pulse at the conclusion of the procedure was 80, and although her blood pressure was 64 systolic, 40 diastolic, there was no evidence of shock.

During her postoperative convalescence she ran a temperature of from 100 to 101°F for several days, otherwise it was normal.

Blood examination on December 13 showed counts of 2,250,000 red blood cells and 15,000 white blood cells, and a hemoglobin of 52 per cent. A stained smear showed a polymorphonuclear leukocytosis. On December 21 the count was 3,200,000 red blood cells, with a hemoglobin of 65 per cent.

Comment Time was wasted in visiting this patient at home, she should have been transported immediately to the hospital.

Abdominal cesarean section on a separated placenta when the baby is known to be dead is not the most conservative method. Had this cervix been dilated sufficiently to allow the rupture of the membranes, and if cervix and vagina had been packed tightly with gauze and a Spanish windlass applied to the fundus, it is probable that the outcome would have been just as successful without the attendant risk of a laparotomy.

This is another case of complete separation of the

placenta with a dead baby that showed no evidence of a toxemia. With a blood pressure of only 64 systolic, transfusion at the close of the operation should have been seriously considered.

TREASURER'S REPORT COVERING REFUND DISTRIBUTION

THE Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1938

The Council voted to distribute the sum of \$4000 to district societies. The total number of payments of annual dues received by the Treasurer by March 2, to be counted for the refund, was 3784. Therefore the refund to the district societies for each paid fellow is \$1.0570.

The following table gives the number of payments in, and the refund to, each district as of March 25

District	Number Reported Paid	Refund
Barnstable	36	\$38.08
Berkshire	100	105.72
Bristol North	55	58.17
Bristol South	165	174.42
Essex North	152	160.67
Essex South	198	209.28
Franklin	40	42.31
Hampden	254	268.49
Hampshire	47	49.71
Middlesex East	104	109.95
Middlesex North	99	104.66
Middlesex South	759	802.27
Norfolk	633	669.09
Norfolk South	100	105.72
Plymouth	106	112.06
Suffolk	518	547.53
Worcester	335	354.12
Worcester North	83	87.75
	3784	\$4000.00

In 1937, for comparison, the total number of payments for the refund was 3734.

CHARLES S. BUTLER, M.D., *Treasurer*

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 4

BARNSTABLE

Sunday, April 10, at 4 00 p. m., at the Cape Cod Hospital, Hyannis. Subject: Differential Diagnosis and Treatment of Scarlet Fever. Instructor: Charles F. McKhann, Jr. John I. B. Vail, *Chairman*.

BERKSHIRE

Thursday, April 7, at 4 30 p. m., at the House of Mercy Hospital, Pittsfield. Subject: Gonorrhea in the Male. Instructor: Oscar F. Cox, Jr. Melvin H. Walker, Jr., *Chairman*.

BRISTOL SOUTH (Fall River Section)

Monday, April 4, at 4 30 p. m., at the Union Hospital, Fall River. Subject: The Use of Vitamins in Pediatric Practice. Instructor: Louis K. Diamond. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*.

ESSEX NORTH

Friday, April 8, at 4 30 p. m., at the Lawrence General Hospital, Lawrence. Subject: The Use of Vitamins in Pediatric Practice. Instructor: Harold L. Higgins. John Parr, *Chairman*.

FRANKLIN

Wednesday, April 6, at 8 00 p. m., at the Franklin County Hospital, Greenfield. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: Marshall N. Fulton. Halbert G. Stetson, *Chairman*.

HAMPDEN

Thursday, April 7, at 4 00 p. m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p. m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject: Early Syphilis. Instructor: William P. Boardman. George D. Henderson and George L. Schadt, *Chairmen*.

HAMPSHIRE

Wednesday, April 6, at 4 15 p. m., in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject: Rheumatic Infection, Rheumatic Heart Disease. Instructor: Benedict F. Massell. Warren P. Cordes, *Chairman*.

MIDDLESEX SOUTH

Wednesday, April 6, at 4 00 p. m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject: Cesarean Section. Analgesia. Instructor: Roy J. Heffernan. Edmund H. Robbins, *Chairman*.

NORFOLK

Friday, April 8, at 8 30 p. m., at the Norwood Hospital, Norwood. Subject: Puerperal Sepsis. Instructor: A. Gordon Gauld. Hugo B. C. Riemer, *Chairman*.

NEW FELLOWS APPROVED BY THE COUNCIL

In the minutes of the meeting of the Council, held on February 2, 1938, it is stated, under the heading of Incidental Business, that the secretary presented a list of applicants for fellowship which had been received too late for publication prior to the meeting of the boards of censors on November 4, 1937. These individuals were admitted to the examination and were tentatively passed. The Council voted to approve the action taken and to declare these physicians fellows of the Massachusetts Medical Society.

Inadvertently the list of names was omitted. However,

the list had been published in the *Journal* for January 6, 1938, and is as follows

ESSEX NORTH DISTRICT

Kay, Julius—Lawrence General Hospital, Lawrence
Tufts College Medical School, 1937

ESSEX SOUTH DISTRICT

Freedberg, Alan Phillips—360 Essex Street, Salem
Rush Medical College, University of Chicago, 1935
Hobbs, Wayne—1 Prescott Road, Lynn
Harvard Medical School, 1935

SUFFOLK DISTRICT

Higgins, Francis Henry—Boston City Hospital, Boston
Harvard Medical School, 1934
Hurwitz, Alfred—Beth Israel Hospital, Boston.
Johns Hopkins University School of Medicine, 1933
O'Brien, Francis Robert—Boston City Hospital, Boston
Tufts College Medical School, 1935

ACTIVITIES OF THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH IN 1937

It is my privilege to give you a brief summary of the work carried on by the Massachusetts Department of Public Health during the past year. The problem of a healthy population is of individual importance to every resident of Massachusetts.

Many significant events took place in the department during 1937. Doubtless the farthest reaching in its effect on the public health of the State was the report submitted to the legislature in December, 1936, by the Special Commission appointed in 1935 to study and investigate public health laws and policies. All phases of public health activities were studied, and many changes in legislation recommended. Altogether, fifty-eight bills were presented for consideration. It is with much gratification that I can report that fourteen of the fifty-eight recommendations were enacted into law. Others were referred to the next annual session to be taken up again or reintroduced in an amended form.

Three of the laws place upon the department important new responsibilities. Chapter 332 provides for the care of certain premature infants. Under this law boards of health are required, upon request of the physician or parent of the premature infant, to provide transportation to a hospital equipped to care for such infants, and if the parents are unable to pay for such hospital care, it becomes the responsibility of the board of public welfare. The Division of Child Hygiene of the department has co-operated with maternity hospitals throughout the State to see that they have proper equipment and trained nursing personnel to care for premature infants.

Chapter 393 is an act for the hospitalization of patients with chronic rheumatism. The term "chronic rheumatism" comprises a group of diseases the most evident symptoms of which usually appear in the joints. This group of diseases is of grave social and economic import. It is estimated that over 5000 persons in the State are totally disabled and about 140,000 crippled to some degree. The incidence among the poor is about 50 per cent higher than among the well-to-do.

Chapter 391 transfers to the Commonwealth the responsibility for the treatment of persons having genito-

infectious diseases, who are unable to pay for private medical care. The vast amount of work on a state wide basis which this legislation entailed made a new division necessary. The Subdivision of Venereal Diseases, formerly part of the Division of Communicable Diseases, was changed to the Division of Genito-infectious Diseases.

An interesting feature of the work of the department is that being done for crippled children. Federal grants from the United States Public Health Service and Children's Bureau made possible the establishment of ten clinics throughout the State. Seven hundred crippled children have been admitted to these clinics. During the year 1423 clinic visits were made and over 2000 physiotherapy treatments given either in the patients' homes or in a central gathering place. One hundred and eighty-four children were admitted to hospitals for surgery or to be fitted with apparatus to correct deformities. These clinics take care of underprivileged children who would not otherwise receive proper treatment.

Five more communities passed regulations requiring the pasteurization or certification of all milk sold locally. This brings to thirty-seven the number of communities that have protected their citizens from milk-borne diseases.

The Division of Communicable Diseases reports that the past year was characterized by the lowest case rate and the lowest death rate for diphtheria in the history of Massachusetts. On the other hand, paratyphoid fever and whooping cough were more prevalent than in any previous year. A total of 97,185 cases of communicable diseases was reported during the year, compared with 106,110 for 1936. Most of the difference was due to a lower incidence of measles and mumps.

Lobar pneumonia continued to show high incidence. For the second year the pneumonia program was carried on entirely at state expense. An increasing number of physicians are making use of the serums supplied free by the State to combat deaths from pneumonia. The Massachusetts pneumonia program is attracting attention all over the country, and is an important addition to the health work carried on by the department.

Not a single case of rabies in human beings was reported during the year. Rabies in animals increased, with most reported cases coming from Essex, Middlesex, Norfolk and Worcester counties. Forty-four communities conducted dog immunization clinics to aid in controlling this disease.

For the sixth consecutive year no smallpox was reported in the State. The value of compulsory vaccination for school children cannot be too strongly stressed as the means of wiping out this terrible disease which used to ravage the State every few years.

The Division of Tuberculosis reports that the number of children treated for tuberculosis had dropped so low that it was possible to close three children's wards at the Westfield State Sanatorium. This is the most outstanding evidence of the value of the tuberculosis control program that has been carried on in the State for the past forty years.

A new cancer tuberculosis unit, providing 50 beds for the treatment of cancer and 144 for tuberculosis, was added to the Westfield State Sanatorium. This new unit which maintains outpatient service for both diseases, will be of inestimable value to the western part of the State. The beds for cancer are already occupied, and but few vacant ones remain for tuberculosis.

The three state laboratories report an increase in their activities. Work at the Antitoxin and Vaccine Laboratory has been materially affected by the increasing impor-

¹ Green Lights to Health, broadcast given by Dr. Henry D. Chadwick on Wednesday, March 23, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

placenta with a dead baby that showed no evidence of a toxemia. With a blood pressure of only 64 systolic, transfusion at the close of the operation should have been seriously considered.

TREASURER'S REPORT COVERING REFUND DISTRIBUTION

THE Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1938.

The Council voted to distribute the sum of \$4000 to district societies. The total number of payments of annual dues received by the Treasurer by March 2, to be counted for the refund, was 3784. Therefore the refund to the district societies for each paid fellow is \$1 0570.

The following table gives the number of payments in, and the refund to, each district as of March 25.

District	Number Reported Paid	Refund
Barnstable	36	\$38 08
Berkshire	100	105 72
Bristol North	55	58 17
Bristol South	165	174 42
Essex North	152	160 67
Essex South	198	209 28
Franklin	40	42.31
Hampden	254	268 49
Hampshire	47	49 71
Middlesex East	104	109 95
Middlesex North	99	104 66
Middlesex South	759	802 27
Norfolk	633	669 09
Norfolk South	100	105 72
Plymouth	106	112 06
Suffolk	518	547.53
Worcester	335	354 12
Worcester North	83	87 75
	3784	\$4000 00

In 1937, for comparison, the total number of payments for the refund was 3734.

ACTIVITIES OF THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH IN 1937

It is my privilege to give you a brief summary of the work carried on by the Massachusetts Department of Public Health during the past year. The problem of a healthy population is of individual importance to every resident of Massachusetts.

Many significant events took place in the department during 1937. Doubtless the farthest reaching in its effect on the public health of the State was the report submitted to the legislature in December, 1936, by the Special Commission appointed in 1935 to study and investigate public health laws and policies. All phases of public health activities were studied, and many changes in legislation recommended. Altogether, fifty-eight bills were presented for consideration. It is with much gratification that I can report that fourteen of the fifty-eight recommendations were enacted into law. Others were referred to the next annual session to be taken up again or reintroduced in an amended form.

Three of the laws place upon the department important new responsibilities. Chapter 332 provides for the care of certain premature infants. Under this law boards of health are required, upon request of the physician or parent of the premature infant, to provide transportation to a hospital equipped to care for such infants, and if the parents are unable to pay for such hospital care, it becomes the responsibility of the board of public welfare. The Division of Child Hygiene of the department has cooperated with maternity hospitals throughout the State to see that they have proper equipment and trained nursing personnel to care for premature infants.

Chapter 393 is an act for the hospitalization of patients with chronic rheumatism. The term "chronic rheumatism" comprises a group of diseases the most evident symptoms of which usually appear in the joints. This group of diseases is of grave social and economic import. It is estimated that over 5000 persons in the State are totally disabled and about 140,000 crippled to some degree. The incidence among the poor is about 50 per cent higher than among the well-to-do.

Chapter 391 transfers to the Commonwealth the responsibility for the treatment of persons having genito-

infectious diseases, who are unable to pay for private medical care. The vast amount of work on a state wide basis which this legislation entailed made a new division necessary. The Subdivision of Venereal Diseases, formerly part of the Division of Communicable Diseases, was changed to the Division of Genitoinfectious Diseases.

An interesting feature of the work of the department is that being done for crippled children. Federal grants from the United States Public Health Service and Children's Bureau made possible the establishment of ten clinics throughout the State. Seven hundred crippled children have been admitted to these clinics. During the year 1423 clinic visits were made and over 2000 physiotherapy treatments given either in the patients' homes or in a central gathering place. One hundred and eighty-four children were admitted to hospitals for surgery or to be fitted with apparatus to correct deformities. These clinics take care of underprivileged children who would not otherwise receive proper treatment.

Five more communities passed regulations requiring the pasteurization or certification of all milk sold locally. This brings to thirty-seven the number of communities that have protected their citizens from milk-borne diseases.

The Division of Communicable Diseases reports that the past year was characterized by the lowest case rate and the lowest death rate for diphtheria in the history of Massachusetts. On the other hand, paratyphoid fever and whooping cough were more prevalent than in any previous year. A total of 97,185 cases of communicable diseases was reported during the year, compared with 106,110 for 1936. Most of the difference was due to a lower incidence of measles and mumps.

Lobar pneumonia continued to show high incidence. For the second year the pneumonia program was carried on entirely at state expense. An increasing number of physicians are making use of the serums supplied free by the State to combat deaths from pneumonia. The Massachusetts pneumonia program is attracting attention all over the country, and is an important addition to the health work carried on by the department.

Not a single case of rabies in human beings was reported during the year. Rabies in animals increased, with most reported cases coming from Essex, Middlesex, Norfolk and Worcester counties. Forty-four communities conducted dog immunization clinics to aid in controlling this disease.

For the sixth consecutive year no smallpox was reported in the State. The value of compulsory vaccination for school children cannot be too strongly stressed as the means of wiping out this terrible disease which used to ravage the State every few years.

The Division of Tuberculosis reports that the number of children treated for tuberculosis had dropped so low that it was possible to close three children's wards at the Westfield State Sanatorium. This is the most outstanding evidence of the value of the tuberculosis control program that has been carried on in the State for the past forty years.

A new cancer tuberculosis unit, providing 50 beds for the treatment of cancer and 144 for tuberculosis, was added to the Westfield State Sanatorium. This new unit which maintains outpatient service for both diseases, will be of inestimable value to the western part of the State. The beds for cancer are already occupied, and but few vacant ones remain for tuberculosis.

The three state laboratories report an increase in their activities. Work at the Antitoxin and Vaccine Laboratory has been materially affected by the increasing impor-

¹ Green Lights to Health—broadcast given by Dr. Henry D. Chadwick on Wednesday, March 23, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

tance of pneumonia and decreasing incidence of diphtheria. During the January floods, at the request of the United States Public Health Service, we sent 87,000 cc. of vaccine to the flooded areas of Kentucky and Ohio. The Wassermann Laboratory reports a new high level for the number of examinations done. Nearly 200,000 blood examinations were made, an increase of about 50,000 specimens. The Bacteriological Laboratory had an exceptionally busy year, due to three paratyphoid outbreaks, several outbreaks of dysentery, and a great increase in the number of specimens of sputum submitted from pneumonia patients. The laboratory continues to act as a training center for laboratory technicians who come for instruction in pneumococcus typing from laboratories approved by the State for pneumonia serum distribution.

The Division of Child Hygiene reports many successful projects carried out during the year. In addition to the premature infant program previously referred to, many other educational programs were continued. Postgraduate courses for physicians throughout the State were carried on in five centers, and a "refresher" course for physicians interested in well-child conferences was held in conjunction with the Harvard School of Public Health, Boston Lying in Hospital, and other institutions. Audiometer testing to determine the hearing sensitivity of school children was carried on successfully in many towns. The work of this division is widespread and covers every field of child health care.

The Division of Adult Hygiene continued its research work with cancer, diabetes and arthritis. Two new clinics were opened bringing the number of state-aided cancer clinics to twenty-one.

In addition to its usual work, the Division of Sanitary Engineering participated in eight special investigations concerning water supplies and sewage-disposal problems. Reports on these studies have been submitted to the legislature. Their investigation of trailer camps indicated that facilities for water supply and sewage disposal at such camps have shown decided improvement, as compared with conditions found two years ago.

In the Division of Food and Drugs, 18,835 samples were examined in 1937, an increase of about 1500 over the previous year. Violations of the mattress law were reduced more than 50 per cent, and ice-cream and soft-drink plants in general showed much improvement over the preceding year.

In this brief time it is impossible to go farther into the work of the department, but this may give you a general idea of the extremely varied fields of health work carried on by the State. The past year was a healthy one for Massachusetts, and one productive of increased opportunities for broadening the field of the department's activities.

Q When you speak of the remarkable drop in tuberculosis, does it mean that tuberculosis is now nearly wiped out?

A. By no means. Because the number of people dying from tuberculosis is declining each year and the death rate is but 43 per 100,000 as compared with 243 at the beginning of the century, many people believe that it is no longer a menace. Unfortunately this is not so. It is still the leading cause of death in the age group from twenty to forty. Great strides have been made in reducing the incidence of this widespread disease, but there is still much to be done. Only constant vigilance on the part of doctors and health authorities, and ready co-operation on the part of parents of suspicious cases, or patients who have already contracted the disease, will bring tuberculosis down to the minimum toward which the State is striv-

ing. It is a major health problem, and there must be no slackening in the efforts made to control it.

Q You spoke of the pneumonia program becoming an integral part of the state health work. What particular work was accomplished in this field during recent years that would warrant its being taken over by the State?

A. Following a five year study carried on by the department with the aid of the Commonwealth Fund it was determined that serums prepared for certain of the thirty two types of pneumonia were curative when administered early in the disease. To make this available to physicians it was necessary to train laboratory technicians to examine the sputum of patients suspected of having pneumonia. This was done and there are now eighty approved hospital laboratories in the State where physicians can have the typing done. Serums for five types of pneumonia are furnished by the department without charge to the patient. Several hundred pneumonia deaths annually can be saved by the use of these serums for the cases in which they are indicated.

Q In your talk about the work done with crippled children you said that the work was only for children who could not otherwise receive medical care. How do you find these children?

A. The children are referred by doctors to one of our clinics which are held monthly in ten cities. They vouch for the children's need of care, and for the inability of the families to pay for proper attention. In this way we are able to give aid where it is most needed to persons under twenty-one years of age. No one is accepted without a physician's recommendation.

Q The Division of Food and Drugs must have many interesting features. What do you consider the most outstanding event in that department during the year?

A. There is little doubt that the most important event in the Division of Food and Drugs was the adoption of the phosphatase test for distinguishing between properly and improperly pasteurized milk. This chemical test can be done on milk taken from any milk wagon and does away with the former necessity of the inspector's being at the pasteurization plant at just the right moment during the pasteurization process, to see whether it was being properly conducted. By this test it can be determined accurately whether milk has been kept at the proper temperature for sufficient time to kill bacteria. Routine examinations with the phosphatase test have been given for the past five months, and the number of alleged pasteurized samples that proved upon testing to be improperly processed have decreased rapidly.

Q Can premature infants be taken care of at any hospital, or is special equipment necessary?

A. About 1000 premature infants die within the first month of life. In certain hospitals with special equipment and nurses trained for this work the death rate for these infants is only half that in the State as a whole. Special equipment and care are necessary for premature infants, and the department is working on a network of hospital centers that will be available to every part of the State. There are now thirty-four of these hospital centers established, and there will be nearly fifty when this part of the program is completed.

Q What, exactly, is meant by a "premature infant"?

A. The law defines a premature infant as one weighing five pounds or less. They need special care. There are many infants weighing more than five pounds who are feeble and in need of special care. We hope that eventually this program will help improve the standard

of care of all such infants and their mothers, and thus save the lives of 400 or 500 babies each year

Q Is it true that the trickling filter for sewage treatment at the department's Experiment Station in Lawrence was the forerunner of the present trickling filter now in use in many cities and that the Massachusetts Department of Public Health was a pioneer in such matters?

A. Yes, the Experiment Station of the department was the first of its kind established on this continent and probably the first of its kind in the world. In this station were developed most of the basic data on which modern methods of treatment of water and sewage have been founded, and it was also at this station that our present methods for the bacterial examination of water were advanced. As a result of the experiments done at this station, Massachusetts has established procedures for the protection of its water supplies, so that at present about 98 per cent of the population live in communities that have safe water supplies. We are singularly free from water borne diseases, one of which is typhoid fever. A generation ago this disease sickened 2000 or 3000 Massachusetts residents each year. Now it is a rare disease, and this State has the lowest typhoid fever death rate in the country.

DEATHS

COLEMAN—ROBERT M. COLEMAN, M.D., of 42 Church Street, Wellesley, died March 24. He was in his forty fifth year.

Born in Wellesley, he attended the Wellesley schools and Phillips Exeter Academy and received his degree from Tufts College Medical School in 1921. During the World War he was in the naval reserve. Dr. Coleman was a former night superintendent at the Boston City Hospital. He was a former fellow of the Massachusetts Medical Society.

His widow, his mother and a brother survive him.

LUNDWALL—LAURENCE S. B. LUNDWALL, M.D., of 81 Main Street, Gardner, died February 11. He was in his sixty second year.

Dr. Lundwall received his degree from the University of Illinois College of Medicine in 1905. He was a fellow of the Massachusetts Medical Society and a member of the American Medical Association.

MONCRIEFF—WILLIAM A. MONCRIEFF, M.D., of 17 South 6th Street, New Bedford, died December 18, 1937. He was in his forty-eighth year.

Dr. Moncrieff received his degree from Tufts College Medical School in 1913. He was a fellow of the Massachusetts Medical Society, a member of the American Medical Association and a member of the New England Otological and Laryngological Society.

WHITE—BENJAMIN WHITE, Ph.D., died suddenly in Southern Pines, North Carolina, on March 28. He was in his sixtieth year.

Born in Cooperstown, New York, on January 15, 1879, he received Ph.B. and Ph.D. degrees from Yale University in 1900 and 1903. Following postgraduate study in Berlin, Munich, Vienna and London, he was made assistant director of the Department of Bacteriology, Hoagland Laboratory, Brooklyn, New York, in 1903, and was director of this department from 1907 until 1914, except for a two-year period which was spent at Saranac, New York, on account of his health. While at Saranac he was an assistant in the Saranac Lake Laboratory. In 1914 he re-

turned to New York as an assistant director of the Bacteriological Laboratories of the New York City Department of Health and in 1920 was appointed director, Division of Biological Laboratories, Massachusetts Department of Public Health. This position he held until his retirement in 1933, his chief duty being the supervision of the Antitoxin and Vaccine Laboratory at Forest Hills. For the past few years he had lived in New York City, and in addition to serving as a consultant to the Commonwealth Fund, recently completed a book *The Biology of Pneumococcus*, which was published by the Commonwealth Fund as a part of their program covering the serum treatment of pneumonia.

At the time of his retirement he was assistant professor of bacteriology and hygiene, Department of Bacteriology, and assistant professor of preventive medicine and hygiene, Department of Preventive Medicine and Hygiene, Harvard Medical School, and lecturer in immunology and instructor in the biological assaying of drugs at the Massachusetts College of Pharmacy. He was an honorary fellow of the Massachusetts Medical Society, a fellow of the National Academy of Arts and Sciences and a member of the National Tuberculosis Association, the American Association of Pathologists and Bacteriologists, the Society of American Bacteriologists, the American Public Health Association, the Society of Experimental Biology and Medicine and the American Association of Immunologists. During the War, he served as a captain in the Sanitary Corps. He had been a member of the editorial board of the *New England Journal of Medicine* for many years.

He is survived by his widow, Nona (Solari) White, whom he married in 1935.

MISCELLANY

CHICAGO TUMOR INSTITUTE

The Chicago Tumor Institute, a nonprofit organization, located at 21 West Elm Street, Chicago, was opened March 21. It offers consultation service to physicians in the diagnosis and treatment of cancer and radiation facilities for cancer patients. The institute also proposes to conduct research and to offer training to physicians who may wish to qualify as specialists in the study and treatment of this disease.

The members of the Scientific Committee are: Max Cutler, M.D., director, Sir G. Lenthal Cheatle, F.R.C.S., Henri Coutard, M.D., Arthur H. Compton, Ph.D., and Ludvig Hektoen, M.D. The Board of Trustees is composed of the following: Ludvig Hektoen, president, Arthur H. Compton, vice president, Roy C. Osgood, treasurer, Modie J. Spiegel, Mrs. Francis Neilson, Mrs. Arthur Meeker, Alfred Busiel, and Max Cutler.

NOTES

The Council of Child Neurology Research announces that applications for grants will be considered at the meetings to be held in April and October of each year. The purpose of the council is to encourage original research on the definite problems coming within the scope of child neurology and allied fields. Applications must be in the hands of the director, Dr. Bernard Sachs, 116 West 59th Street, New York City, before April 1 and September 15. The applicant must state distinctly the problem under investigation and the methods to be pursued.

tance of pneumonia and decreasing incidence of diphtheria. During the January floods, at the request of the United States Public Health Service, we sent 87,000 cc. of vaccine to the flooded areas of Kentucky and Ohio. The Wassermann Laboratory reports a new high level for the number of examinations done. Nearly 200,000 blood examinations were made, an increase of about 50,000 specimens. The Bacteriological Laboratory had an exceptionally busy year, due to three paratyphoid outbreaks, several outbreaks of dysentery, and a great increase in the number of specimens of sputum submitted from pneumonia patients. The laboratory continues to act as a training center for laboratory technicians who come for instruction in pneumococcus typing from laboratories approved by the State for pneumonia serum distribution.

The Division of Child Hygiene reports many successful projects carried out during the year. In addition to the premature infant program previously referred to, many other educational programs were continued. Postgraduate courses for physicians throughout the State were carried on in five centers, and a "refresher" course for physicians interested in well-child conferences was held in conjunction with the Harvard School of Public Health, Boston Lying in Hospital, and other institutions. Audiometer testing to determine the hearing sensitivity of school children was carried on successfully in many towns. The work of this division is widespread and covers every field of child health care.

The Division of Adult Hygiene continued its research work with cancer, diabetes and arthritis. Two new clinics were opened bringing the number of state-aided cancer clinics to twenty-one.

In addition to its usual work, the Division of Sanitary Engineering participated in eight special investigations concerning water supplies and sewage-disposal problems. Reports on these studies have been submitted to the legislature. Their investigation of trailer camps indicated that facilities for water supply and sewage disposal at such camps have shown decided improvement, as compared with conditions found two years ago.

In the Division of Food and Drugs, 18,835 samples were examined in 1937, an increase of about 1500 over the previous year. Violations of the mattress law were reduced more than 50 per cent, and ice-cream and soft-drink plants in general showed much improvement over the preceding year.

In this brief time it is impossible to go farther into the work of the department, but this may give you a general idea of the extremely varied fields of health work carried on by the State. The past year was a healthy one for Massachusetts, and one productive of increased opportunities for broadening the field of the department's activities.

Q When you speak of the remarkable drop in tuberculosis, does it mean that tuberculosis is now nearly wiped out?

A By no means. Because the number of people dying from tuberculosis is declining each year and the death rate is but 43 per 100,000 as compared with 243 at the beginning of the century, many people believe that it is no longer a menace. Unfortunately this is not so. It is still the leading cause of death in the age group from twenty to forty. Great strides have been made in reducing the incidence of this widespread disease, but there is still much to be done. Only constant vigilance on the part of doctors and health authorities, and ready co-operation on the part of parents of suspicious cases, or patients who have already contracted the disease, will bring tuberculosis down to the minimum toward which the State is striv-

ing. It is a major health problem, and there must be no slackening in the efforts made to control it.

Q You spoke of the pneumonia program becoming an integral part of the state health work. What particular work was accomplished in this field during recent years that would warrant its being taken over by the State?

A Following a five year study carried on by the department with the aid of the Commonwealth Fund it was determined that serums prepared for certain of the thirty two types of pneumonia were curative when administered early in the disease. To make this available to physicians it was necessary to train laboratory technicians to examine the sputum of patients suspected of having pneumonia. This was done and there are now eighty approved hospital laboratories in the State where physicians can have the typing done. Serums for five types of pneumonia are furnished by the department without charge to the patient. Several hundred pneumonia deaths annually can be saved by the use of these serums for the cases in which they are indicated.

Q In your talk about the work done with crippled children you said that the work was only for children who could not otherwise receive medical care. How do you find these children?

A The children are referred by doctors to one of our clinics which are held monthly in ten cities. They vouch for the children's need of care, and for the inability of the families to pay for proper attention. In this way we are able to give aid where it is most needed to persons under twenty-one years of age. No one is accepted without a physician's recommendation.

Q The Division of Food and Drugs must have many interesting features. What do you consider the most outstanding event in that department during the year?

A There is little doubt that the most important event in the Division of Food and Drugs was the adoption of the phosphatase test for distinguishing between properly and improperly pasteurized milk. This chemical test can be done on milk taken from any milk wagon and does away with the former necessity of the inspector's being at the pasteurization plant at just the right moment during the pasteurization process, to see whether it was being properly conducted. By this test it can be determined accurately whether milk has been kept at the proper temperature for sufficient time to kill bacteria. Routine examinations with the phosphatase test have been given for the past five months, and the number of alleged pasteurized samples that proved upon testing to be improperly processed have decreased rapidly.

Q Can premature infants be taken care of at any hospital, or is special equipment necessary?

A About 1000 premature infants die within the first month of life. In certain hospitals with special equipment and nurses trained for this work the death rate for these infants is only half that in the State as a whole. Special equipment and care are necessary for premature infants, and the department is working on a network of hospital centers that will be available to every part of the State. There are now thirty-four of these hospital centers established, and there will be nearly fifty when this part of the program is completed.

Q What, exactly, is meant by a premature infant?

A The law defines a premature infant as one weighing five pounds or less. They need special care. There are many infants weighing more than five pounds who are feeble and in need of special care. We hope that eventually this program will help improve the standard

lege of traveling with professional friends on our Special." A little later on, a printed itinerary will be issued in which interesting variations of return routes will be briefly outlined.

We hope we may have the privilege of having a good many of your members with us and all reservations will receive our most careful attention.

BLOOD SAMPLES FOR SUGAR DETERMINATIONS

To the Editor Bloods submitted to laboratories for the determination of blood sugar are often valueless due to a misunderstanding of the proper way of preserving such specimens. Potassium oxalate prevents clotting of blood but does not prevent glycolysis. If analyses of blood for sugar cannot be made immediately, or within an hour after the blood is taken, a preservative must be added. A crystal of thymol, a drop or two of formalin, or a few milligrams of sodium fluoride are preservatives commonly employed. At this laboratory the preservative used is sodium fluoride. A mixture of 20 mg. of potassium oxalate and 50 mg. of sodium fluoride will prevent clotting and glycolysis of 10 cc. of blood for at least five days at icebox temperature, and for about three days at normal room temperature. A few crystals of potassium oxalate and as much sodium fluoride as will fit easily on the tip of a penknife is equally effective.

Chemical Laboratory

New England Deaconess Hospital,
Deaconess Road,
Boston, Massachusetts.

REPORT OF MEETING

THE HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on January 11. Dr. C. Sidney Burwell presided.

The first case to be presented was that of a 44-year-old Italian chef who had come to this country at the age of 6. Before that time he had lived in his father's tavern in Italy. Ten years before entry he had had an attack of mild epigastric pain. Four and a half years before entry he suddenly became black and fainted. He was studied at that time, and a cholecystectomy done. Since then he had had intermittent bouts of jaundice, epigastric pain and clay-colored stools. In October of last year, 3 months before entry, he had had a similar but more severe attack and was admitted to the Peter Bent Brigham Hospital. The liver was found to be 2 cm. below the right costal margin and a circular shadow was seen in the right lobe of the liver by x-ray. An eosinophilia of 25 per cent was present and the skin test for echinococcus disease was positive. He was sent home and reentered in December for operation. Many adhesions and a mass in the head of the pancreas were found, and on irrigation of the common duct, daughter echinococcus cysts were recovered. A drain was inserted into the common duct and the cholecystectomy was completed.

of gelatinous material containing daughter cysts. Dr. Cutler discussed the case and pointed out that this patient had a typical history of this condition and that the attack of cyanosis and unconsciousness were due to the anaphylactic shock which accompanies the rupture of the mother cyst.

A 48-year-old Lithuanian was presented as the second case. Her chief complaint on entry was orthopnea and dyspnea of 4 months duration. Her sister had had rheumatic heart disease and her husband rheumatic fever. The patient gave a history of pneumonia at the age of 14 followed by joint pains for 3 months. At the age of 31, in her fourth pregnancy, she was found to have the signs of mitral stenosis and regurgitation with mild decompensation. At this time she was seen by Dr. Paul D. White and was followed by his clinic for 5 years. She did well until 4 years before entry when she again became decompensated and had ascites and pleural effusion. In August 1937, she again showed evidence of cardiac failure and was admitted to the Peter Bent Brigham Hospital in December for similar symptoms. Physical examination at that time showed an emaciated, dark-skinned woman, dyspneic and with considerable congestion of the neck veins. There were signs of a bilateral pleural effusion. The left border of dullness of the heart was 12 cm. to the left of the midsternal line. The mitral first sound was accentuated, with a systolic and presystolic murmur present in this area. A systolic and a short early diastolic murmur were present at the base, and she was fibrillating at an apical rate of 60. The blood pressure was 120/70. Thrills could be felt over both apex and base. The abdomen was distended and a right upper-quadrant mass pulsated expansilely. Edema of the legs and over the sacrum was present. Laboratory data showed evidence of kidney congestion, and the venous pressure was 140 mm. of water in both arms. An electrocardiogram showed right-axis deviation and auricular fibrillation. X-rays of the chest demonstrated fluid on the right and a markedly enlarged heart with a prominence along the left border typical of rheumatic heart disease, calcified valves were seen.

Doctors Burwell, White and Levine discussed the case and pointed out the probability of tricuspid stenosis in a case with such long standing systemic failure. A patient with involvement of the aortic, mitral and tricuspid valves has a more favorable prognosis than one with aortic or mitral lesions alone. A large liver over a period of years in a case of rheumatic heart disease should make one suspect tricuspid valve involvement.

Dr. Burwell introduced the speaker of the evening, Dr. Paul D. White, who presented the history of the development of our knowledge of the cardiovascular system and its diseases. For the past few years Dr. White has made this a hobby and has collected many of the early editions of the authors who have made substantial additions to such knowledge. He displayed many of these volumes. Dr. White has also devised a chart showing the development of knowledge of the circulation from century to century. He has divided this chart into two parts: on the left he has shown the developments in anatomy and physiology and on the right side in parallel fashion he has put pathology and medicine, thus effectively showing the importance of knowledge of the fundamental medical sciences before advances in clinical medicine are made.

The science of hygiene was an important part of early medicine and the earliest written medical records also speak of the use of squill and opium. The Alexandrian school increased anatomical knowledge considerably. In 300 A.D. Galen's work on the circulation of the blood was

The trustees of Tufts College have established a laboratory for research in sensory psychology and physiology, which will be under the direction of Dr Leonard Carmichael, who was recently elected president of the college. Bertram Wellman, now research associate in psychology at the University of Rochester, an expert in the application of electrical technics to psychological and physiological problems, will become assistant director of the laboratory.

Among honorary degrees conferred by Boston University on March 14, Founders Day, was the doctorate of science on Dr William E Chenery, laryngologist and trustee of Boston University

CORRESPONDENCE

CANCER MONTH

To the Editor In connection with the national observance of April as cancer month, the Massachusetts Cancer Program will publicize routine work that is being done throughout the year. In addition to this, a few extra radio broadcasts will be given, and at the completion of one of the regular cancer clinics at each of the twenty-one state-aided clinics, a special cured-cancer clinic will be given. During the first six years of the cancer program approximately one thousand individuals appeared at the clinics who have now been free from cancer for five years or more. About three hundred of these will be present at the special clinics. The following is a schedule of the clinics

<i>Cancer Clinic</i>	<i>Date and Hour</i>	<i>Consultant</i>
Beth Israel—April 21, 11 00 a. m.—	Staff of Beth Israel.	
Boston Dispensary—April 29, 11 30 a. m.—	Staff of Dispensary *	
Brockton—April 12, 11 00 a. m.—	Dr Thomas Anglem	
Cape Cod Hyannis—April 26, 4 00 p. m.—	Dr W M Shedden	
Fall River—April 28, 11 00 a. m.—	Dr J V Meigs	
Fitchburg—April 5, 10 00 a. m.—	Dr Ernest Daland	
Gardner—April 8, 10 00 a. m.—	Dr L S McKittrick	
Gloucester—April 20, 10 00 a. m.—	Dr E P Hayden	
Greenfield—April 1, 10 00 a. m.—	Dr Richard Wallace	
Lawrence—April 26, 10 00 a. m.—	Dr C C Simmons	
Lowell—April 27, 6 00 p. m.—	Dr H Marun, N Y	
Lynn—April 22, 10 00 a. m.—	Dr E. M. Daland.	
New Bedford—April 13, 4 00 p. m.—	Staff of St. Luke's	
Newburyport—April 5, 10 00 a. m.—	Dr C C Franseen	
North Adams—April 28, 4 00 p. m.—	Dr Charles Lund	
Northampton—April 21, 4 00 p. m.—	Dr C C Simmons	
Pittsfield—April 26, 4 00 p. m.—	Dr E. M. Daland	
Pondville—April 20, 3 00 p. m.—	Dr Daland and staff	
Springfield—April 1, 4 00 p. m.,	Dr A W Oughterson	
New Haven.		
Westfield—April 13, 4 00 p. m.—	Dr Daland and staff	
Worcester—April 27, 10 30 a. m.—	not decided	

With Dr H M Clute and Dr G W Taylor as consultants

Every community in which a Co-operative Cancer Control Committee has been organized will have some of its member organizations invite a local physician to speak during the month. It is estimated that there will be upward of one thousand such meetings, with a combined attendance of nearly twenty thousand individuals.

Special radio broadcasts on cancer will be given. The following is a schedule of these talks

WAAB April 6, 8 15 p. m. 'Public Health Aspects of Cancer' by Henry D Chadwick, M.D.

WEEL April 8, 4 15 p. m. 'Fallacies and Facts About Cancer and Cancer Control' by Lila O Burbark, M.D.

WAAB April 13, 8 15 p. m. 'Cancer The disease by Joseph C Aub, M.D.

WEEL April 15, 7 30 p. m. Cancer by Shields Warren, M.D.

For several years Dr Lombard has been making a study of the familial aspects of cancer, his report is completed and will be published in the *New England Journal of Medicine* during the month.

For the past five years work has been progressing on the preparation of a satisfactory code to transcribe the cancer statistical data to punch cards so that the statistical analysis may be facilitated. This is a pioneer type of work, and we have no knowledge of its having been done elsewhere. The completion of this undertaking marks an epoch in the field of cancer statistics. Requests for the completed code have already come from several cancer hospitals in different parts of the country. April will mark the beginning of the transcription of these records to the permanent punch cards.

Throughout the program, the medical profession has co-operated with the department in furnishing advice, in helping with the cancer clinics, in speaking before the public, and in giving unstintingly of enthusiastic support. I take this opportunity of expressing my sincere appreciation.

HENRY D CHADWICK, M.D.,
Commissioner of Public Health

State House,
Boston, Massachusetts

SUSPENSION OF LICENSE

To the Editor This is to inform you that at the meeting of the Board of Registration in Medicine held March 17, it was voted to suspend for six months the license of Dr Solomon Gobert, 141 Meridian Street, East Boston, because of testimony in court.

STEPHEN RUSHMORE, M.D., *Secretary,*
Board of Registration in Medicine.

State House,
Boston, Massachusetts

CHICAGO MEDICAL SOCIETY SPECIAL

To the Editor We are writing to call attention of the members of the Massachusetts Medical Society to the operation of a Chicago Medical Society Special train from Chicago to San Francisco in connection with the American Medical Association sessions in June. Our train will be routed over the Milwaukee Road from Chicago to Omaha, Union Pacific to Ogden, and Southern Pacific to San Francisco, leaving Chicago from the Union Station at 9 00 p. m., Thursday, June 9, arriving San Francisco at 8 30 a. m., June 12.

The Chicago Medical Society Special will be composed of the most modern type, air-conditioned Pullman sleeping car equipment, with lowers, uppers, compartments, drawing rooms, and single and double bedrooms, and will have all the refinements that one can find on a high grade train. It will be operated on a fast schedule, and there will be no excess fare involved, regular passenger fares applying from your home town.

If your Society does not contemplate the operation of a special train, the members of your organization are cordially invited to travel to San Francisco on this train with us. We feel confident that they will enjoy the privi-

lege of traveling with professional friends on our Special." A little later on, a printed itinerary will be issued in which interesting variations of return routes will be briefly outlined.

We hope we may have the privilege of having a good many of your members with us and all reservations will receive our most careful attention.

REPORT OF MEETING

THE HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on January 11. Dr C. Sidney Burwell presided.

The first case to be presented was that of a 44-year-old Italian chef who had come to this country at the age of 6. Before that time he had lived in his father's tavern in Italy. Ten years before entry he had had an attack of mild epigastric pain. Four and a half years before entry he suddenly became black and fainted. He was studied at that time, and a cholecystectomy done. Since then he had had intermittent bouts of jaundice, epigastric pain and clay-colored stools. In October of last year, 3 months before entry, he had had a similar but more severe attack and was admitted to the Peter Bent Brigham Hospital. The liver was found to be 2 cm. below the right costal margin and a circular shadow was seen in the right lobe of the liver by x-ray. An eosinophilia of 25 per cent was present and the skin test for echinococcus disease was positive. He was sent home and reentered in December for operation. Many adhesions and a mass in the head of the pancreas were found, and on irrigation of the common duct, daughter echinococcus cysts were recovered. A drain was inserted into the common duct and the abdomen closed. Following operation there has been irregular, intermittent drainage

of gelatinous material containing daughter cysts. Dr Cudde discussed the case and pointed out that this patient had a typical history of this condition and that the attack of cyanosis and unconsciousness were due to the anaphylactic shock which accompanies the rupture of the mother cyst.

A 48-year-old Lithuanian was presented as the second case. Her chief complaint on entry was orthopnea and dyspnea of 4 months duration. Her sister had had rheumatic heart disease and her husband rheumatic fever. The patient gave a history of pneumonia at the age of 14 followed by joint pains for 3 months. At the age of 31, in her fourth pregnancy, she was found to have the signs of mitral stenosis and regurgitation with mild decompensation. At this time she was seen by Dr Paul D. White and was followed by his clinic for 5 years. She did well until 4 years before entry when she again became decompensated and had ascites and pleural effusion. In August 1937, she again showed evidence of cardiac failure and was admitted to the Peter Bent Brigham Hospital in December for similar symptoms. Physical examination at that time showed an emaciated, dark skinned woman, dyspneic and with considerable congestion of the neck veins. There were signs of a bilateral pleural effusion. The left border of dullness of the heart was 12 cm. to the left of the midsternal line. The mitral first sound was accentuated, with a systolic and presystolic murmur present in this area. A systolic and a short early diastolic murmur were present at the base, and she was fibrillating at an apical rate of 60. The blood pressure was 120/70. Thrills could be felt over both apex and base. The abdomen was distended and a right upper-quadrant mass pulsated expansilely. Edema of the legs and over the sacrum was present. Laboratory data showed evidence of kidney congestion, and the venous pressure was 140 mm of water in both arms. An electrocardiogram showed right-axis deviation and auricular fibrillation. X-rays of the chest demonstrated fluid on the right and a markedly enlarged heart with a prominence along the left border typical of rheumatic heart disease, calcified valves were seen.

Doctors Burwell, White and Levine discussed the case and pointed out the probability of tricuspid stenosis in a case with such long standing systemic failure. A patient with involvement of the aortic, mitral and tricuspid valves has a more favorable prognosis than one with aortic or mitral lesions alone. A large liver over a period of years in a case of rheumatic heart disease should make one suspect tricuspid valve involvement.

Dr Burwell introduced the speaker of the evening, Dr Paul D. White, who presented the history of the development of our knowledge of the cardiovascular system and its diseases. For the past few years Dr White has made this a hobby and has collected many of the early editions of the authors who have made substantial additions to such knowledge. He displayed many of these volumes. Dr White has also devised a chart showing the development of knowledge of the circulation from century to century. He has divided this chart into two parts: on the left he has shown the developments in anatomy and physiology and on the right side in parallel fashion he has put pathology and medicine, thus effectively showing the importance of knowledge of the fundamental medical sciences before advances in clinical medicine are made.

The science of hygiene was an important part of early medicine and the earliest written medical records also speak of the use of squill and opium. The Alexandrian school increased anatomical knowledge considerably. In 30 A.D., Celsus summarized medical knowledge which had been accumulated up to that time. Dioscorides in

60 A.D. wrote a work on *materia medica* that was the authority on the subject until relatively modern times Galen (born about 131 A.D.) studied the heart and arteries in animals, wrote about the pulse, and was acquainted with all of the arrhythmias. Medical schools were founded in Italy around 1100 A.D. These were the important contributions before 1500.

In the sixteenth century autopsies began to be done, cases of pericarditis and big hearts were described, and the relation of aneurysms to syphilis was recognized. It was then gradually realized that heart disease as such could exist, before that time such a possibility was not admitted, doubtless largely because postmortem examinations had not been made. Vesalius published his epochal anatomy in 1543 and gave a description of the heart and circulation, including briefly the coronaries. In the seventeenth century the first treatise on heart disease was written, the valves of the veins were described, Harvey wrote his monumental work on the circulation of the blood (1628), the thoracic duct was discovered, and Malpighi described the capillaries (1661). Toward the end of the century (1679) Bonetus published his important work *Sepulchretum*, an extensive compilation of autopsies done up to that time.

In the first half of the eighteenth century three authoritative books on heart disease were written (Vieussens, 1715, Lancisi, 1728, Senac, 1749). During this century many important contributions were made. The coronary circulation was described as well as the cardiac nerve supply. The first blood pressure study was made by Hales in 1733. The use of percussion in the physical examination of the chest was first described by Auenbrugger (1761), Withering introduced foxglove for dropsy (1785), and angina pectoris as a clinical entity was recognized by Heberden (1768). Pulmonary vascular congestion in mitral stenosis was described by Vieussens (1715), engorgement of the veins of the neck in dilatation of the right heart chambers by Lancisi (1728), and quinine for obstinate palpitation and venesection for pulmonary edema were advised by Senac (1749). Cases of heart block with syncope were described by Morgagni (1761) and confirmed in the next century by Adams and Stokes. Jenner, about 1775, recognized the connection between angina pectoris and coronary disease, confirmed by Parry in 1799.

In the nineteenth century many more contributions made their first appearance. In 1806 Corvisart published his classical book on heart disease. In 1815 Hodgson wrote on vascular disease. Mediate auscultation and the stethoscope were introduced by Laennec in 1819, and in 1825 Stokes in Great Britain advised the use of the stethoscope. In 1832 Hope described left ventricular failure and cardiac asthma. In 1836 Williams wrote on nervous palpitation, reviving the ancient view of Galen and his contemporaries. In 1842 Chevers described a case of chronic constrictive pericarditis and explained its pathogenesis. In 1858 Peacock wrote the first book on congenital malformations of the heart. In 1872 Gull and Sutton described arteriolar sclerosis, and in 1878 Welch produced pulmonary edema experimentally. The first human electrocardiogram was taken in 1887 by Waller. X-ray examination of the chest was made in 1896, a few months after the introduction of this method of study by Roentgen, in that year Francis Williams of Boston demonstrated an x-ray picture of the heart in Washington at the spring meeting of the Association of American Physicians.

From 1900 on, Dr. White found it very difficult to pick out the most important contributions because of the wealth

of material and the closeness to our own time. Among those he chose are Mackenzie's studies of the pulse, Wenckebach's work on cardiac arrhythmias, Krogh's study of the capillaries, investigations of blood pressure, the modern electrocardiograph (first introduced by Einthoven in 1903), Lewis's study of the mechanism of the heart beat, the description of coronary thrombosis by Herrick in 1912, Cabot's contribution on the etiology of heart disease in 1914, and the establishment of cardiac specialization and of the heart journals in various countries in the last two decades.

NOTICES

ANNOUNCEMENT

JOSIAH E. QUINCY, M.D., announces that, beginning April 1, he will continue the practice of the late Dr. Charles Day at the same address, 270 Commonwealth Avenue, Boston.

FAULKNER HOSPITAL

The usual clinicopathological conference will be held at the Faulkner Hospital for its staff and other interested members of the medical profession on Thursday, April 7, at 5 00 p. m.

There will be a discussion of cases by Dr. Burton E. Hamilton and Dr. Charles P. Sheldon.

J. B. HAZARD, M.D., *Secretary*

AMERICAN NEISSERIAN MEDICAL SOCIETY

The fourth annual session of the American Neisserian Medical Society will be held in Washington, D. C., on May 16 and 17 in the Public Health Auditorium located at 19th Street and Constitution Avenue, N. W.

The session will open with a symposium on sulfanilamide, which will be timely and of great value to every one. Dr. Perrin H. Long, of the Johns Hopkins Hospital, will deliver the principal address. Dr. Long's work puts him in the position of being the country's leading authority on the chemistry, mode of action and clinical use of sulfanilamide. Following the presidential address in the afternoon there will be simultaneous meetings of the three following sections: Male Clinical, Female Clinical, Laboratory and Research. The Male Clinical Section will discuss in considerable detail the question of nomenclature, standard record forms, diagnosis and cure. The Female Clinical Section will discuss diagnosis and cure. The Laboratory and Research Section will discuss bacteriology, serology and research. The reports of these deliberations as accepted on the following day will become the society's official opinion and will serve as authoritative information which when disseminated will undoubtedly result in clarifying some of the present needless confusion. This would seem to be an important step toward improving the management and control of gonorrhea. The chairmen of the sections desire all possible assistance from the members, who are urged to attend and take an active part in the deliberations of the section meeting most in line with their interests.

The second day will open with the business meeting following which the sections will submit their reports. There will be ample opportunity for generous discussion before the reports are accepted. The final afternoon will be devoted to the presentation of some extremely interesting papers.

OSCAR F. COX, M.D., *Secretary*

REMOVAL

GEORGE W. PAPER, M.D., announces the removal of his office to 31 Milk Street, Room 1020, Boston

TUFTS ALUMNI LECTURE

The annual alumni lecture of the Tufts Alumni Association will be held at the Tufts College Medical School, on Wednesday, April 6, at 4:00 p. m.

Dr. George W. Holmes, roentgenologist to the Massachusetts General Hospital and clinical professor of roentgenology at Harvard, will speak on Pulmonary Bleeding. Its cause and diagnosis with special consideration of the roentgenological findings.

Medical students and physicians are cordially invited to attend.

HARRY BLOTNER, M.D., *Secretary*

EASTERN HAMPDEN
MEDICAL ASSOCIATION

Because of conflict with the Thursday evening lecture of the Postgraduate Extension Course, the next monthly meeting of the Eastern Hampden Medical Association will be held on Wednesday, April 6, at 4:45 p. m., at the Oaks Hotel, Springfield.

Dr. R. E. Dickson, of Holyoke, will present the scientific paper entitled "Undulant Fever." Case reports will be given by Dr. Edith E. Baldwin and Dr. H. F. Cleveland.

The medical profession is cordially invited to attend.

J. JOSEPH KLAR, M.D., *Secretary-Treasurer*

BOSTON DISPENSARY

25 Bennet Street, Boston
Lecture Hall, Second Floor, 9-10 a. m.

MEDICAL CONFERENCE PROGRAM, APRIL, 1938

- Friday, April 1—Specific Therapy for Certain Anemias of Childhood. Louis K. Diamond
Saturday, April 2—Pneumonia. Dr. Joseph H. Pratt.
Tuesday, April 5—Diagnosis and Treatment of Certain Bone Tumors. Dr. John D. Adams.
Wednesday, April 6—Hospital Case Presentation. Dr. S. J. Thannhauser
Thursday, April 7—Social-Service Case Presentation. Mrs. H. B. Hooker and Miss E. Grundy
Friday, April 8—The Pathogenesis of Pulmonary Edema. Dr. Sidney Farber
Saturday, April 9—Management of Acute Empyema. Dr. Henry L. Cabott.
Tuesday, April 12—Vitamin A Deficiency in Adults. Dr. Harold J. Jeghers
Wednesday, April 13—Hospital Case Presentation. Dr. S. J. Thannhauser
Thursday, April 14—Transurethral Prostatic Resection. Dr. P. N. Papas and Dr. Harold A. Chamberlin
Friday, April 15—Acid Base Balance in Health and Disease. Dr. John H. Talbott.
Saturday, April 16—Hospital Case Presentation. Dr. S. J. Thannhauser
Wednesday, April 20—Hospital Case Presentation. Dr. S. J. Thannhauser
Thursday, April 21—Follow up of Interesting Diagnostic Problems. Presentation of former Diagnostic Hospital patients. Dr. H. G. Brugsch

Friday, April 22—Surgery of Peripheral Vascular System. Dr. James C. White.

Saturday, April 23—Hospital Case Presentation. Dr. S. J. Thannhauser

Tuesday, April 26—Clinicopathological Conference. Dr. R. C. Wadsworth and Dr. Cadis Phipps.

Wednesday, April 27—Hospital Case Presentation. Dr. S. J. Thannhauser

Thursday, April 28—The Significance of the Heterophile Agglutination Test. Dr. Peter Beer

Friday, April 29—Social Security. Professor E. B. Wilson

Saturday, April 30—Hospital Case Presentation. Dr. S. J. Thannhauser

SYMPOSIUM IN HONOR
OF DR. JELLIFFE

The thirty-fifth anniversary of Dr. Smith Ely Jelliffe's editorship of the *Journal of Nervous and Mental Diseases* will be celebrated at the New York Academy of Medicine on April 22.

A neuropsychiatric symposium will be opened by Dr. Adolph Meyer at two o'clock in the afternoon; Dr. Jelliffe will preside. The scheduled speakers and subjects are as follows: Dr. Earl D. Bond, 'Balance in Psychiatric Research'; Dr. George Draper, 'The Man Factor in Disease'; Dr. Frederick Tilney, 'New Interpretation of the Hippocampus'; Dr. Oskar Diethelm, 'Psychiatry and Neurology in the Last Fifty Years'; Dr. Karl Menninger, 'Somatic Correlations with the Unconscious Repudiation of Femininity in Women.' This will be followed by a dinner in the evening, at which Dr. Foster Kennedy will be toastmaster; the speakers include Drs. Abraham A. Brill, Louis Casemajor, Henry A. Riley and Richard H. Hutchings.

WACHUSETT MEDICAL
IMPROVEMENT SOCIETY

The next meeting of the Wachusett Medical Improvement Society will be held at the Holden District Hospital, on Wednesday evening, April 6. Dinner at 6:30 will be followed by a business meeting at 7:30.

SCIENTIFIC PROGRAM

The Administrative Side of the Hospital. Dr. G. A. MacIver, superintendent of Worcester City Hospital, and Dr. G. H. Stone, superintendent of the Memorial Hospital.

Irrigation vs. Vaccine vs. Sulfanilamide in the Treatment of Gonorrhea. Dr. N. S. Scarcello, junior urologist, Worcester City Hospital.

WALTER D. BIEBERBACH, M.D., *President*
NICHOLAS S. SCARCELLO, M.D., *Secretary*

GREATER BOSTON MEDICAL SOCIETY

There will be a meeting of the Greater Boston Medical Society at the Beth Israel Hospital Auditorium on Tuesday, April 5, at 8:30 p. m.

Dr. Louis Nahum, assistant professor of physiology at the Yale University School of Medicine, will speak on 'Comments on the Coronary Arteries from the Clinical Standpoint with Special Reference to Prognosis.'

K. C. ROSEN, M.D., *President*
D. B. STEARNS, M.D., *Secretary*

NEW ENGLAND DERMATOLOGICAL SOCIETY

The annual meeting of the New England Dermatological Society will be held on Wednesday afternoon, April 13, at the Boston City Hospital in the Skin Outpatient Department at 3 00

BERNARD APPEL, M.D., *Secretary*

BOOK REVIEWS

Primary Carcinoma of the Lung Edwin J. Simons 263 pp. Chicago: The Year Book Publishers, Inc., 1937 \$5.00

This book is an exhaustive study of the more than 550 articles comprising the literature on primary carcinoma of the lung. In all, about 5000 proved cases are mentioned in the literature, but most of the tables in the present work concern only parts of this total number.

From his study, the author draws the following conclusions. There has been a real and not merely an apparent increase of pulmonary carcinoma. Fourteen possible etiologic agents have been mentioned, all of which produce chronic pulmonary irritation. Macroscopically, pathologic specimens may be hilar or peripheral, histologically, the cases may be grouped under (1) squamous cell, (2) adenocarcinoma, (3) undifferentiated round or spindle cell growths. All three types originate from one parent cell—the undifferentiated basal cell of the bronchial epithelium. The so-called Pancoast tumor is simply pulmonary carcinoma in a peculiar location. In most cases pleural "endothelioma" is metastatic carcinoma. The right and left upper lobes are almost equally involved but the right lung more frequently than the left if all the lobes are taken into account. Metastases occur in the order of decreasing frequency in the following organs: regional lymph nodes, liver, lungs, bones, kidneys, adrenals, pleurae, brain, pericardium, pancreas, cervical nodes, heart, thyroid and spleen. Eighty per cent of pulmonary carcinoma occurs in males. Eighty per cent of all cases occur between the ages of forty and seventy. There are only fourteen cases reported in persons nineteen years of age or younger. The symptoms arranged in order of decreasing frequency are as follows: cough, expectoration, pain, dyspnea, emaciation, fever, hemoptysis, dilated chest veins, cyanosis, edema and night sweats. The author then goes on to discuss signs, special laboratory examinations, roentgenological appearance, and finally, treatment.

Thirty pages of tables do not convince the reviewer of the truth of the first conclusion, but the rest are in line with accepted opinion.

The work is advertised as a book by a general practitioner for general practitioners, but it will find its principal use as a reference work for physicians and surgeons who are specializing in diseases of the lung. Most general practitioners will get what they need in a shorter time by reading one or two of the briefer articles by outstanding authorities in the field.

The work lacks force because the writer has had very little clinical experience with the condition he is discussing, and has no sound basis for evaluating the statements of other writers. But the literature is very well surveyed, and the book will be of real value to all who are interested in the subject.

Physiological Chemistry of the Bile Harry Sobotta. 202 pp. Baltimore: The Williams & Wilkins Company, 1937 \$3.00

This volume should be an extremely useful reference book for those who are interested in the study of biliary tract physiology. The title is somewhat misleading, inasmuch as the physiology of the bile pigments is not considered, but the author justifies their exclusion from this volume because of the extent of the subject. He very justly points out the vastness of the literature on the subject of biliary secretion, with the comment that its extensiveness is more imposing than its depth. It is obvious

that he has attempted to clarify many of the discrepancies to be found in the clinical and experimental studies of bile acids, and he has succeeded extremely well. With a great deal of care he points out that bile fistula studies, because of varying techniques, cannot be readily correlated. In some instances, for example, a bile fistula has been a gall bladder fistula with its striking factor of concentration, while at other times it has truly represented a hepatic or common duct fistula with its more diluted hepatic secretion.

Careful definitions of chologogic action, choleresis and cholangenesis are timely, and are important contributions to a much confused conception of biliary tract physiology. The discussion of the effect of bile acids on these functions, as well as on the processes of digestion and enzyme activity, on micro-organisms and in immune reactions, together with that of the pharmacologic action of bile salts, is complete and interesting. The complex chemistry of the bile acids is well presented but leaves the reader more or less in a state of confusion, probably because clarity in this field is still an impossible achievement.

In addition to the excellent summary on the choleric action of bile acids, it is interesting and pleasing to read a fairly authoritative review on the chologogic and choleric effects of various drugs. Calomel is neatly laid in its grave as an inert substance, so far as being a secretory stimulant is concerned. Data on the physiologic activity of dehydrocholic acid (decholin) are given in full, and are of real interest. It is a matter of regret that the clinical use of this preparation has not fulfilled the estimates of its usefulness, as suggested by experimental data.

The author has done well to bury another ghost, namely the therapeutic effect of oil administered orally in dissolving or evacuating gallstones.

Without doubt the book is essentially a complete exposition of the literature on the various aspects of bile acids, and the voluminous bibliography of forty-four pages is an imposing one. The author indulges in no verbiage, and does much in his comments to clarify a distinctly difficult and confusing subject. Futile speculation on most points he labels as such. For the practitioner the volume is detailed and arrives at too few definite conclusions to offer immediate practical aid. The rare clinical observations are not always on a par with the general excellence of the book. To the investigator the book should prove an invaluable source of information and comment on a most interesting but bewildering subject.

Practical Proctology Louis A. Buie. 512 pp. Philadelphia and London: W. B. Saunders Company, 1937 \$6.50

The author has presented a most complete and convincing exposition of diseases of the anus and rectum, based largely on his own tremendous experience. Throughout the entire book there is very clear evidence of careful analysis of the facts obtained from innumerable observations made over a period of years. There is also a very distinct and comforting attitude of practical common sense that makes the volume an excellent basis for reference.

The author states: "In the past ten years once every two days a paper on disease of the colon, rectum or anus has appeared in some accredited medical journal. Amid much that is confusing in all these articles, his book stands out with extreme clarity in all its details. He stresses throughout the importance of careful examination and absolute insistence that any rectal lesion should be considered malignant until proved otherwise. The anatomical descriptions in the book are very clear and are given in great detail."

Surgical technic is described in detail but is easily read. At times the author is rather caustic in his criticism of various maneuvers but always justifiably so. Traditional methods are scrutinized carefully and are frequently discarded because of their complete lack of rationality. In commenting on surgical methods he quite rightly says "One can only describe technic, it cannot be taught."

Certain statistical facts are of interest and are clearly presented. The traditional conception that anal fistula and tuberculosis are commonly associated is convincingly disproved. The use of dilators is frequently, and quite properly, condemned. The supposed relation of retroversion of the uterus to anal and rectal disturbances is clearly discussed and discarded. The entire discussion of hemorrhoids, including the injection method of treatment, is very fairly and successfully presented. The chapter on anal pruritus is a masterpiece and describes the patient, his complaints and their treatment in a manner that can only be based on an unusual experience.

The chapter on polyps is complete, and quite properly the author insists upon radical treatment of all such lesions because of the subsequent danger of cancer. Factual ulcer of the rectum due to radiation of pelvic organs receives adequate attention, and it is important that this frequently overlooked sequel to what may have been a necessary therapeutic procedure is properly emphasized.

The chapter on ulcerative colitis is of interest, and from the point of view of description, leaves nothing to be desired. Remarks upon treatment and prognosis are worded with extreme caution, however, and consist largely in quotations from others. The author has quite wisely refrained from discussing end results in what is obviously a controversial subject.

Syphilis as a traditional cause for rectal stricture is fairly shown to be almost a negligible factor. Lymphopathia venerea is extremely well described, particularly in its relation to stenosing lesions in the rectum, but one wonders why it is differentiated from lymphogranuloma in guinea.

Adverse criticism can find little place in a discussion of this book. The attitude of the writer is always that of a surgeon but is consistently conservative and always convincing. One regrets that there is very little appreciation of the functional disturbances which are so frequently encountered by medical men. This is reflected, for example, in the dietary suggestions for treatment of constipation, which, according to the author, should consist of high residue or high roughage diets—a form of treatment which has been long known to be contraindicated in many cases.

Aside from such minor criticisms, there can be little question that the book is extremely valuable in every respect. The illustrations are numerous and well prepared. The volume is a distinct addition to the literature on the subject.

Concepts and Problems of Psychotherapy Leland E. Hinsie. 199 pp. New York: Columbia University Press, 1937. \$2.75.

The aim of this volume is to discuss and evaluate the general conceptions of psychotherapy in its relation to clinical psychiatry, particularly as based upon the current concepts of mental functioning. It raises important issues in the field of psychiatry.

The author points out that psychotherapy may be roughly divided into ante-Freudian methods (suggestion, general discussion, hypnosis), and the Freudian method of psychoanalysis with its complicated theoretical ramifications and practical therapeutic application. In psychoanalysis, the concepts of analytical psychology (Jung) and

of individual psychology (Adler) had their origin, while psychobiology is a very general term which, according to Adolf Meyer, is an investigation of the interaction of human beings with various environments, and evaluates the activities and capacities of the individual.

There is a critical examination of the various schools of psychotherapy and a discussion of the difficulties of the evaluation of the results. It is pointed out that psychoanalysis can be used only in a small percentage of the total number of patients who seek or require it, partly due to the limited number of qualified analysts and partly because only certain types of cases seem amenable to an analytic therapy. The best results of therapeutic analysis are obtained in the psychoneuroses, sexual perversions and inversions. The author suggests that psychotherapy must eventually submit its data to biometric analysis, such as has already been done in tuberculosis.

Chapter V, by Dr. Carney A. Landis, on the statistical evaluation of psychotherapeutic methods, appears to the reviewer to be one of the most valuable and practical sections for the physician. Here it is pointed out that any therapeutic method must satisfy several major considerations, that it must be rational and effective and that there must be a logical relation between the therapeutic agent employed and the result or cure. In psychological medicine (psychotherapy) these considerations are difficult to evaluate for several reasons. The exact nature of nervous or mental disease is unknown. There may be a disagreement of opinion as to exact etiology (somatic, psychogenic, or both). The relation between therapy and result is less clear than in organic conditions, and finally, there is no uniformity of opinion as to what constitutes an amelioration or cure. Therefore, statistical figures in the field of psychotherapy have to be evaluated cautiously.

Several tables are given from various hospitals, arranged according to diagnostic groups. It is impossible to go into the details of these tables within the limits of a review, except to state that they show that for every ten patients in mental hospitals four are discharged as recovered or improved. The figures vary, of course, with sex, age level and type of mental disease. These figures are compared with reports from institutes which utilize specific psychotherapeutic methods. In the Berlin Psychoanalytic Institute, cases were termed recovered when the symptoms disappeared. The neuroses showed the best recovery rate. A few of the figures, relating to recovered cases or to those much improved, may be summarized as follows: Maudsley Hospital 67 per cent, Cassel Hospital 70 per cent, New York State Psychiatric Institute 87 per cent, Berlin Psychoanalytic Institute 58 per cent in all cases and 91 per cent in completed cases. These figures seem to show that no one type of intensive therapy is more effective than another.

While the author, as a rule, is cautious in discussing the various concepts in mental structure and function and how these influence different psychotherapeutic methods, yet the reviewer must point out that assembled statistics fail to give a genuine picture of what has been accomplished. In the opinion of the reviewer, there are certain neurotic disorders which can be handled without prolonged and deep therapy, provided their dynamic structure is understood, but it was not until the advent of psychoanalysis that such a dynamic evaluation of symptoms could be reconstructed. It must be emphasized that for the more severe and protracted psychoneuroses or character disorders, the therapy of choice is psychoanalysis, as most cases of this type, according to their clinical histories, have had other psychotherapeutic methods and have not been favorably influenced by this surface ploughing.

NUMBER 14

ACUTE POSTOPERATIVE DUODENAL FISTULA

A Report of 12 Cases

MARSHALL K. BARTLETT, M.D.,* AND W. HOLBROOK LOWELL, M.D.†

BOSTON

DUODENAL fistula is a most distressing but fortunately a rare postoperative complication. Colp,¹² writing in 1923, reported 61 cases, of which 53 were collected from the literature. The mortality in this series was 51 per cent. Bohrer and Milici⁵ added 44 cases from 1923 to 1931. The mortality in this group was 18 per cent, giving a combined mortality of 37 per cent in 105 cases.

In what we believe to be a complete review of the literature from 1865 to 1937, a total of 130 reported cases of postoperative duodenal fistula were found. Establishing an arbitrary period of three months as the maximum postoperative interval during which a duodenal fistula may be considered of the acute type, and excluding those cases in which insufficient data are available, we reduce this total to 116 cases. To this we now add 12 cases from the records of the Massachusetts General Hospital for the past twenty years. A brief summary of each of our own cases appears at the end of this paper. Each has been carefully studied in the hope of obtaining information which may help in treating similar patients in the future. Critical remarks are added to most of the case summaries. It should be kept clearly in mind that many of these patients were treated some years ago, and statements made from the vantage point of our present more complete knowledge of this condition should not be construed as criticism of the actual treatment.

There are two general types of duodenal fistula: the lateral type, in which the opening is in the duodenal wall but the continuity of the gastrointestinal tract remains intact, and the end type, in which the fistula results from leakage from the closed duodenal stump following gastric resection or pyloric occlusion. In the latter group, the continuity of the gastrointestinal tract has of course

been interrupted and re-established by some form of gastrojejunostomy.

That the end type is much less common and a much more benign condition than the lateral type is shown by the fact that the former occurred in only 14 cases in the entire series of 128, with but 2 deaths, a mortality of 14 per cent, while the mortality of the 114 cases with the lateral type was 40 per cent.

The surgical procedures which preceded the development of the fistula have been divided into groups and listed in order of numerical importance in Table 1. These procedures cannot in them-

Table 1 *Surgical Procedures Preceding Onset of Fistula.*

PROCEDURE	NO. OF CASES
Gastric surgery including resection for cancer or ulcer, gastroenterostomy and pyloric occlusion	23
Right nephrectomy for cancer, hydronephrosis and pyonephrosis, nephrolithiasis and perinephric abscess	22
Duodenorrhaphy for perforated duodenal ulcer with or without gastroenterostomy	17
Cholecystectomy for acute or chronic cholecystitis and cholelithiasis	15
Combined surgery on the extrahepatic biliary system and the upper gastrointestinal tract	15
Cholecystostomy for acute cholecystitis	8
Exploration of the common duct with or without cholecystectomy	8
Incision and drainage of an abscess in the right upper quadrant	7
Suture of a traumatic rupture of the duodenum	5
Miscellaneous operations with accidental perforation of the duodenum	5
Resection of a duodenal diverticulum	1
Incision and drainage of an appendix abscess	1
Appendectomy with drainage	1
	128

selves be considered true etiologic factors. There were involved in each operation, however, certain fundamental factors which led to the production of duodenal fistulas. They may be divided into three groups, any combination of which may be present in a given case.

(1) *Trauma.* An unrecognized perforation of the duodenum may be made at the time of operation, or the duodenal wall may be sufficiently traumatized and devitalized so that a spontaneous

*Assistant in surgery, Massachusetts General Hospital.
†Intern, Hartford Hospital, Hartford, Connecticut.

perforation occurs during the postoperative period. Drainage material placed in contact with the duodenal wall may be a contributing traumatic factor in the production of necrosis.

(2) *Sepsis* Infection at the site of operation may cause necrosis of the duodenum and subsequently the development of a fistulous tract.

(3) *Improper healing* That a sutured wound of the duodenal wall does not heal may be caused by the local condition or by various factors in the patient's general condition. Both sepsis and trauma may be local factors interfering with healing. That purulent infection rapidly destroys the tensile strength of catgut has been shown by Howes,²⁰ and that trauma and devitalization interfere with healing is too well known to require discussion. Other important local factors are faulty suture technic or material, the presence of drainage material adjacent to a suture line, and improper hemostasis with the collection of blood or serum, with or without subsequent infection. In addition, various systemic factors may affect the healing of a sutured wound in the duodenum. Howes, Briggs, Shea and Harvey²⁸ have shown that starvation has a retarding effect on wound healing. Lanman and Ingalls³⁰ have recently demonstrated the importance of vitamin-C deficiency in improper wound healing. Dehydration has long been recognized as influencing regeneration of tissue.

With the increasing knowledge of the underlying chemical changes involved in extensive loss of duodenal contents, and with improvement in methods of combating these changes, the mortality statistics have shown a gratifying decline. Table 2

Table 2 *Mortality Rates in Cases with Acute Postoperative Duodenal Fistula*

YEARS	NO. OF CASES	MORTALITY
		%
1901-1905	13	46
1906-1910	5	80
1911-1915	22	59
1916-1920	17	24

1926-1930	26	23
1931-1935	10	10
1935-1937	5	60
Total	128	38

shows the mortality by five-year intervals since 1900, and the number of cases in each five-year period. Credit for the clinical progress reflected in these generally lower mortality figures must be given to a large number of workers. The more important findings follow.

Elman and McCaughan¹⁵ demonstrated the fatal effect on dogs of the total loss of pancreatic juice. Loss of electrolytes and dehydration are factors leading to this result, and life can be prolonged

by parenteral administration of Ringer's solution. Death cannot be prevented by this treatment, however, and occurs after some weeks. It is apparently not due to inanition and the possibility of the loss in the pancreatic secretion of some essential substance other than water and electrolytes has been suggested.

Prolonged loss of gastric secretion will eventuate in death owing to depletion of chlorides, dehydration and alkalosis, and changes in kidney function—the so-called “dehydration kidney.” The gastric secretion itself is not essential to life, but chlorides and water are. This has been amply proved by White and Fender³¹ and by Gamble and Ross.²¹

In experimental animals prolonged loss of bile is compatible with life, as shown by Walters and Bollman.⁷⁵ It does lead, however, to an increase in fibrinogen content and viscosity of the blood, a bleeding tendency, faulty fat metabolism and a lowered blood calcium and phosphorus.

If a sufficiently large proportion of the duodenal contents is lost through the fistula, the patient will soon suffer from nitrogen starvation due to deficient protein intake. This is reflected in a lowering of the serum protein. The work of Jones, Eaton and White³¹ has shown experimentally that this is an important factor in making fluid accumulate in the tissues and producing edema. They emphasize that there are various other important elements in the production of postoperative edema, such as serous drainage, sepsis and the administration of excessive amounts of water and sodium chloride.

Thus in a patient with a duodenal fistula the following chemical mechanisms are brought into play as a result of loss of duodenal contents and starvation.

Blood chlorides fall, owing to the loss of chlorides present in the secretions of the stomach, liver and pancreas. The tissue chlorides follow a course parallel to that of the plasma chlorides.

Sodium bicarbonate is lost in the bile and pancreatic secretion. This loss, together with that of chlorides, tends to decrease the salt concentration of the plasma.

The *carbon-dioxide combining power* of the blood is increased. Loss of hydrochloric acid leaves an excess of base in the plasma which is combined with carbon dioxide to form bicarbonate. The increase in carbon-dioxide combining power does not necessarily parallel the loss of chloride, owing to the increase in ketone bodies and organic acids resulting from faulty metabolism and tissue breakdown.

Dehydration occurs, being due to fluid loss and the inability of the body to retain water in the face

of a falling salt concentration. This leads to a decreased fluid content, increased viscosity of the blood and slowing of the circulation. Cyanosis may occur, and polycythemia and a temporary elevation of the plasma protein may be present.

The *nonprotein nitrogen* of the blood rises after some days. Several factors contribute to this. Kidney excretion may be impaired by faulty circulation, and increased formation of waste products, due to tissue breakdown, may occur.

The *serum protein* falls gradually, on account of insufficient protein intake. The importance of this factor in the production of nutritional edema has been discussed above.

The rapidity with which these changes occur is the result of a balance between the proportion of duodenal contents lost through the fistula on the one hand, and the success of the efforts made to offset this loss on the other.

That extremely large amounts of drainage may occur from a duodenal fistula is well known. Erdman¹⁶ reports the collection of 4000 cc. in a single day. Various factors contribute in determining the amount of drainage. The amount taken by mouth is the most obvious one and needs no discussion. The size and location of the fistulous opening are obvious factors.

In addition to these purely mechanical influences, the muscular activity of the duodenum plays a most important part, as pointed out by Perl.¹⁸ He also emphasizes the increase in peristaltic activity due to duodenal irritation. Normally the duodenal contents are passed to and fro a few times, to promote rapid mixing of food and digestive juices, before passing into the jejunum. The normal intraduodenal pressure is 15 cm. of water, and rises higher during peristaltic activity. This undoubtedly explains why such a large amount of drainage may come from a relatively tiny fistulous opening in the duodenum.

The diagnosis of postoperative duodenal fistula usually presents no great difficulty. Typically the onset is sudden, coming usually within the first two weeks after operation, often immediately following the removal of a drain. It is characterized by a copious alkaline watery discharge from the wound, with rapid and widespread irritation and necrosis of the tissues of the abdominal wall. The diagnosis can usually be easily confirmed by the administration of a dye, such as carmine or methylene blue, by mouth. In the lateral type of fistula the dye appears on the dressing almost at once, while in the end type the interval may be somewhat longer, but the dye generally appears in sufficient quantity to clinch the diagnosis.

The treatment of duodenal fistula falls naturally into two phases: first, adequate local care of

the wound to minimize irritation and digestion of tissue, secondly, systemic treatment to offset so far as possible the effects of the loss of duodenal contents.

It appears from our study that the most important single factor in the local care of the wound is the use of constant suction, to keep it as dry as possible and prevent prolonged contact between the duodenal contents and the tissues of the abdominal wall. Cheever¹⁰ gives credit to Jones and Williams for first advocating this procedure, and most recent writers advocate its use.

In addition to the mechanical removal of irritating substances from the wound, a variety of local applications have been advocated. These may be divided according to their intended action as follows:

- (1) Chemical neutralization of the proteolytic ferments by combining them with an excess of peptone powder, protein and fat, beef juice or Bovinine (Potter,⁶⁰ Warshaw,⁸ Kittelson³⁴). McEvers⁴⁷ has suggested that the same effect may be obtained by the oral administration of boiled milk, acidophilus milk or reliquefied milk concentrate.

- (2) Mechanical adsorption of the ferments by finely divided charcoal, kaolin or bronzing powder.

- (3) Inactivation of the tryptic ferments by producing an acid medium. Irrigation of the wound with N/10 hydrochloric acid (Potter⁶⁰), citric acid (Johanson³⁰) or 5 per cent tannic acid (Perl¹⁸) has been suggested.

- (4) Protection of the surrounding skin by boric ointment, zinc oxide or liquid latex. In our hands it has proved difficult to apply these in such a way that the duodenal contents will not seep under them, thus making the situation worse.

- (5) Elimination of positive intraduodenal pressure by passing a tube into the duodenum, as advocated by Perl¹⁸.

After reading the uniformly successful reports on various combinations of these methods, one must conclude that the extreme care with which the technic is applied is more important than the actual substances used, and that any logical plan of local treatment will, if carried out with sufficient patience and care, yield a satisfactory result.

The importance of early recognition of the fundamental chemical changes resulting from loss of duodenal contents cannot be too strongly stressed. The rapidity with which these changes may develop is illustrated in the abstract of Case 3. This woman was moribund ten days after the establishment of the duodenal fistula. The speed with which such a desperate situation may develop depends on the patient's general condition at the time of operation, and upon the proportion of the

duodenal contents lost through the fistula. Various chemical determinations should be used at frequent intervals to help keep the surgeon informed as to the patient's condition, and to determine the vigor with which the various chemical changes must be combated.

The best clinical guide to an adequate fluid balance is the urinary output. To keep this up to 1500 cc in twenty-four hours in a patient who is losing a considerable amount of fluid through a duodenal fistula requires the administration of large amounts of parenteral fluid. The danger of giving excessive amounts of fluid and sodium chloride, with the resultant production of edema, has already been mentioned, and must be kept constantly in mind.

Glucose must be given in the parenteral fluid to supply tissue demands and replenish glycogen stores in muscle and liver. The carbon-dioxide combining power of the blood must be checked at frequent intervals. The blood nonprotein nitrogen gives an index of the degree of success of the kidneys in eliminating waste products.

The serum-protein level must be frequently determined. Providing an adequate parenteral supply of fluid and salt is a relatively simple problem compared with that supplying a parenteral protein. Blood transfusion is one means of giving the body protein, but in practice it has proved rather ineffective in the face of prolonged nitrogen starvation. Nevertheless, the value of a well-timed blood transfusion as a general stimulant and as a means of combating secondary anemia cannot be overemphasized.

It must be remembered that the treatment of a patient with a duodenal fistula is a long-drawn-out process. The average duration of drainage in our cases was twenty-two days, and the longest single period was six weeks. In dealing with a small fistula with relatively little loss of duodenal contents, local care of the wound, parenteral fluid, salt and glucose, together with transfusion as indicated, may be adequate therapeutic measures.

If the fistula is large and the drainage profuse, the patient's course may be steadily downward in spite of all these efforts. It is in these cases that death occurs, and often the outcome is fatal because the situation becomes desperate before it is recognized as such, and too late for adequate defense measures. Once serious disturbances in body chemistry have developed, effective relief is difficult, and these changes must be foreseen and opposed effectively before they reach grave proportions. It is our belief that in treating serious cases success depends upon early recognition of the inadequacy of the parenteral route by itself, and upon the establishment of an adequate means of introducing substances into the gastrointestinal

tract below the fistula. The advantages are obvious: the drainage from the fistula can be collected and replaced in the intestinal tract, and an adequate caloric intake, including a sufficient supply of protein and vitamins, can be provided.

The exact method of effecting this result must be chosen to fit the particular case. It may be possible to pass a small nasal tube through the stomach and into the duodenum far enough to be effective, or a tube may be successfully introduced through the fistulous tract into the duodenum. The latter procedure seems somewhat hazardous, as it may well delay closure of the fistula. If a functioning gastrojejunostomy is present, the problem may be simplified and tube feeding of the collected drainage may be tried.

If these simpler methods are not effective, a jejunostomy must be done. This should be carried out through a short muscle-splitting incision in the left upper quadrant under local block anesthesia. The tube should enter the bowel at least 15 cm below the ligament of Treitz. The exact method for its insertion by a modified Witzel technic has been well described by Linton.⁴³

The dangers of delay in performing a jejunostomy are illustrated in the abstracts of Cases 1, 3, 4 and 5. It is of course impossible to say that if the operation had been carried out at an earlier date the patients would have survived, but it seems obvious that their chances would have been improved, and we believe that in many cases of duodenal fistula a well-timed jejunostomy will prove to be a lifesaving procedure.

SUMMARY AND CONCLUSIONS

1 Twelve cases of acute postoperative duodenal fistula treated at the Massachusetts General Hospital, together with 116 cases from the literature, are reviewed.

2 There are two general types of duodenal fistula: the lateral and the end types. The latter is less common and more benign.

3 Various local and systemic factors of importance in the production of a duodenal fistula are discussed.

4 Treatment is divided into two phases: local and systemic. Constant suction is the most important single factor in local treatment.

5 The changes in body chemistry resulting from the loss of duodenal contents are briefly discussed.

6 The importance of the prevention of these changes by actively combating them in the early stages is stressed.

7 The early recognition of the need of a jejunostomy is emphasized. We believe this to be a lifesaving procedure in many cases.

CASE REPORTS

Case 1 A man of 35 had had a cholecystectomy and choledochostomy performed in 1918. A catheter was sewed into the common duct. Cholecystostomy had been done 3 years previously at an outside hospital. Thirteen days after the operation, following removal of the catheter and the cigarette wick, profuse bile stained drainage from the wound began. That this was a duodenal fistula was immediately recognized.

The patient's course was steadily downhill in spite of parenteral fluid containing glucose and salt, and attempts at rectal feeding. One month after the appearance of the duodenal fistula, jejunostomy was done under ether anesthesia. Twelve days later the patient died.

Comment The loss of duodenal contents, including in all probability a large part of any food taken by mouth, was allowed to continue for a month, without attempting to collect this material and replace it in the gastrointestinal tract. This case occurred a number of years ago, and no blood-chemistry determinations are available. In view of the length of time that the patient lived after the development of the fistula, it seems more than likely that if a jejunostomy had been done as soon as the fistula appeared, and if the duodenal drainage had been collected and replaced in the jejunum, together with an adequate supply of nourishment, he might well have survived.

Case 2 A man of 40 underwent a cholecystectomy and drainage of subhepatic abscess in 1922. No stones were found. The gall bladder was acutely inflamed. He had a long and stormy convalescence with a persistent biliary sinus and was discharged 3 months after operation, with instructions to return in 1 week for cholecystectomy. On readmission the sinus tract was explored in an attempt to remove the gall bladder. The operation was abandoned on account of uncontrollable oozing. A portion of the sinus tract was removed, and on pathological examination showed tuberculosis. Nine days later a duodenal fistula developed.

Fourteen days after operation an attempt was made to do a jejunostomy through an incision in the left upper quadrant. Dense adhesions were encountered, and the operation was stopped because of profuse bleeding, with out an available loop of bowel having been found. Attempts to get a nasal tube into the duodenum were unsuccessful. Constant suction was used to prevent digestion of the abdominal wall, but repeated hemorrhages from the fistulous tract occurred. Many hypodermoclyses and several transfusions were given, but the patient's condition became steadily worse and he died 3 weeks after the appearance of the fistula.

Autopsy showed extensive tuberculous peritonitis, duodenal fistula and a subhepatic abscess cavity.

Comment It seems according to present concepts that every attempt was made to treat this patient properly. These efforts were unsuccessful because of the nature of the underlying process, which was not definitely identified until autopsy.

Case 3 A woman of 28 had a nephrectomy for tuberculosis of the kidney in 1922. The procedure was technically difficult as the surgeon's note states that the kidney was

freed by cutting masses of scar tissue. Immediate and profuse bile stained drainage from the wound was noted. In spite of a high fluid intake by mouth the urinary output was low. Carmine given by mouth appeared on the dressing in 10 minutes. A diagnosis of duodenal fistula was made. The patient's condition became rapidly and progressively worse. Ten days after the operation jejunostomy was considered, but the patient was deemed too sick to stand the procedure, and she died the next day.

Comment This case illustrates how rapidly a patient's condition can become critical when the defect in the duodenum is large and the drainage profuse. It also illustrates the danger of even a few days' delay in performing a jejunostomy in a case of this type.

Case 4 Six months before entry a man of 55 had had a cholecystectomy for acute cholecystitis, which was followed by a persistent biliary fistula and intermittent jaundice. At operation, performed in 1924, a dilated common duct with an obstruction at its lower end was found. No opening into the duodenum could be discovered and a choledochoduodenostomy was done. The gall bladder was drained.

The wound drained profusely with much skin irritation, and a diagnosis of duodenal fistula was made. The drainage amounted to about 4000 cc. daily, and constant suction was used to keep the wound dry. Parenteral fluid containing salt and glucose was given and transfusion was done. The patient's condition became rapidly worse and he died 19 days after operation.

Autopsy showed obstruction of the common duct due to adenocarcinoma.

Comment In retrospect and in the light of our present knowledge, a jejunostomy should have been done as soon as the profuse drainage was recognized as duodenal contents.

Case 5 Cholecystectomy and choledochostomy were done in 1928 on a man of 49. The operation was technically difficult, and an opening was made in the duodenum in freeing it from the gall bladder. There was some question as to whether a spontaneous fistula between the duodenum and gall bladder had been present. Stones were removed from the common duct and a catheter was inserted for drainage. The duodenum was closed in two layers and the suture line was carefully covered with omentum.

Ten days after operation an abscess developed in the wound, followed by profuse drainage. A diagnosis of duodenal fistula was made, and 10 days later the wound was put on suction. Three weeks after the development of the fistula a jejunostomy was done. Two days after this, fecal drainage from the original wound began, and 3 days later the patient died.

No blood chemistry was done until the day the jejunostomy was performed. At that time the blood nonprotein nitrogen was 90 mg per cent, and the blood chlorides were 462 mg (as sodium chloride) per cent. Three days later the nonprotein nitrogen was 188 mg., and the blood chlorides 578 mg per cent. This patient was given dyes for 10 days after the first operation, and no more parenteral fluid until the day of the second operation.

Comment Here again it seems fair to say that if the seriousness of the situation had been recog-

nized sooner and a jejunostomy had been done at once, rather than allowing the loss of duodenal contents to continue for three weeks, the patient's chances of survival would have been improved. At the present time a loss of duodenal contents would certainly not be allowed to continue so long without administration of parenteral saline and glucose

Case 6 A woman of 33 developed a duodenal fistula following a third operation on the biliary system. The first operation was a cholecystectomy done at another hospital. The second was an exploration for biliary obstruction. A dilated stump of hepatic duct was found, but it was impossible to anastomose this to the duodenum, so a tube was inserted and a biliary fistula established. At the third operation in 1929 this fistulous tract was implanted into the duodenum. Profuse bile-stained drainage began at once, and carmine given by mouth appeared on the dressing immediately.

A diagnosis of duodenal fistula was made, and a week later jejunostomy was done and the original wound was put on suction. The collected drainage was introduced into the jejunostomy tube, together with a concentrated liquid food mixture. Five weeks after operation drainage from the incision stopped, and 3 days later the jejunostomy tube was removed.

The blood chlorides were repeatedly measured, and were kept within normal limits by parenteral fluids as indicated. Ten days later the fistula opened spontaneously and drained for 3 days before closing.

The patient was discharged from the hospital 6½ weeks after operation. Her progress after leaving the hospital was complicated by intermittent bouts of biliary obstruction, and she finally died 3½ years after operation.

Case 7 A man of 27 had an exclusion of the pylorus and a posteriorgastroenterostomy performed for duodenal ulcer in 1929. After 7 days of uneventful convalescence he began to run an unexplained temperature, and soon developed some fluid in the left pleural cavity. Three weeks after operation the wound broke open and began to drain profusely. Carmine by mouth appeared on the dressing within 1 hour. A diagnosis of duodenal fistula was made.

Constant suction was instituted and the wound progressed well. No blood-chemistry determinations are recorded. Drainage ceased, and 7 weeks after operation and 4 weeks after establishment of the fistula the patient was discharged with the wound nearly healed.

Comment This is the only case in our series of the end type of duodenal fistula, and illustrates the relatively benign course of most of these cases.

Case 8 A man of 77 had a resection of the pyloric end of the stomach and a posterior gastroenterostomy performed in 1934. On the 11th postoperative day the wound separated, requiring resuture. Profuse drainage from the wound continued and a diagnosis of duodenal fistula was made.

The case was treated by intravenous glucose in normal saline and by transfusion. Two weeks later the blood chlorides were equivalent to 107 cc. of N/10 hydrochloric acid, and the serum protein was 5.2 gm per cent. A tube was successfully passed through the fistula into the duodenum and feedings were started. Immediate improvement was noted. The serum protein remained at 5.1 gm per cent. The duodenal tube was removed 4

weeks after the establishment of the fistula. There was no further drainage. The patient was discharged 73 days after operation.

Comment This case illustrates the success with which the situation can be kept under control if a tube can be passed through the fistula into the duodenum.

Case 9 A woman of 52 was operated upon for carcinoma of the stomach in 1936. A posterior gastroenterostomy for duodenal ulcer had been done 25 years previously. Abdominal exploration revealed a carcinoma of the stomach, which was amenable to surgical removal. The posterior gastroenterostomy appeared normal. The duodenum was shrunken to a small, thickened, finger-like process. The gastrosolic and gastrohepatic omentums were divided, but at this point the patient's condition became so poor that it was deemed wise to abandon further operation. The wound was closed and the patient was returned to the ward. On the 15th day after operation wound sepsis developed, and the next day profuse bile stained drainage from the wound began. A diagnosis of duodenal fistula was made.

For the next 2 weeks the blood chlorides and the carbon-dioxide combining power were kept within normal limits by means of parenteral fluids. The blood non-protein nitrogen was not elevated, and the urine was negative. The serum protein fell to 4.1 gm per cent. The patient went steadily downhill, and died at the end of this 2 weeks period in spite of repeated transfusions.

Comment It is hard to see how the treatment of this patient, once the duodenal fistula was established, could have been improved, at least as indicated by the various chemical factors measured. With a functioning posterior gastroenterostomy a jejunostomy would probably have been of no advantage. Collection of the duodenal contents discharged from the fistula and refeeding by means of a nasal tube in the stomach, however, might have improved the patient's chances of survival, and should have been tried.

Case 10 A woman of 72 was admitted in 1936 with a diagnosis of acute cholecystitis. She was jaundiced, with a van den Bergh of 8.92 mg per cent and an icteric index of 20. The blood nonprotein nitrogen was 26 mg per cent. The acute attack subsided, and 10 days after admission operation was undertaken. It proved to be a difficult procedure. A much dilated common duct was found and opened. No stones were found in it. The ampulla of Vater was easily dilated and the duct was closed around a T tube. There was a stormy convalescence, with pulmonary collapse at the right base and a low urinary output, in spite of the administration of intravenous glucose in normal saline. The blood nonprotein nitrogen rose to 90 mg per cent and the blood chlorides fell to the equivalent of 69 cc. of N/10 hydrochloric acid.

The wick was removed on the 8th postoperative day and some bleeding from the sinus tract occurred. Two days later some digestion of the skin around the sinus was noted. Twenty-two days after the operation, profuse bile-stained drainage began from the sinus with digestion of the wound. Two days later the patient died.

Comment In this case it appears that the duodenal fistula was only the terminal event. Even

previous to its development the patient's condition was so impaired that her chances of survival were poor, and it is hard to believe that any known treatment of the fistula itself could have altered the outcome.

Case 11 A man of 57 was admitted in 1937 because of jaundice. Five years previously a cholecystostomy had been performed. Two months before admission a cholecystectomy was done because of persistent symptoms. Exploration of the common duct was thought desirable at that time but was not attempted because of the technical difficulties encountered.

At operation the region of the common duct was carefully explored. No patent common duct could be found, even by the transduodenal route, and no dilated bile ducts were located. The subhepatic space was drained. On the 7th day after operation there was a sharp increase in the amount of drainage. That this was caused by a duodenal fistula was quickly recognized, and wound suction was started.

Drainage from the fistula exceeded the oral intake by about 700 cc. in 24 hours. Adequate parenteral fluid was given and the blood-chloride level was kept within normal limits. Four days after the onset the serum protein had fallen to 4.6 gm. per cent. A transfusion of 550 cc. of blood was given. Ten days after establishment of the fistula a definite decrease in the amount of drainage was noted, and the next day the oral intake exceeded the amount of drainage. This positive balance continued to increase rapidly, and the patient's general condition improved steadily. All drainage ceased 19 days after the onset of the fistula and the patient was discharged the next day.

Comment This case illustrates how adequate parenteral fluids and local care will control the situation, at least for a relatively short period of time, in the face of a moderately severe duodenal fistula.

Case 12 A woman of 56 had had a cholecystostomy performed 2 months before operation in 1937. At that time choledochostomy and transduodenal removal of a common duct stone were performed. Nine days after operation, following removal of the wick and tube from the common duct, profuse drainage from the wound began and a diagnosis of duodenal fistula was made.

The drainage amounted to about 500 cc. in 24 hours and was collected by constant suction. The blood chemistry was easily maintained at normal levels by parenteral fluids. Nine days after establishment of the fistula all drainage had ceased, and 5 days later the patient was discharged from the hospital.

Comment This case is an excellent example of a fistula with only a relatively small amount of drainage, in which the situation was easily controlled by local measures and parenteral fluid

THROMBOPHLEBITIS IN THE LEGS

JOHN HOMANS, M.D.*

BOSTON

AS you are well aware, for both the surgeon and the physician thrombophlebitis presents a serious clinical problem. I need not dwell on this. I should like rather to remind you of the basic nature of thrombosis, without knowledge of which a discussion of its clinical behavior is meaningless.

First, and most important, thrombosis takes place only in a blood current—a slow one as a rule. It is not coagulation, or clotting, in which the formation of fibrin is the principal reaction, but rather a deposition of blood platelets, that is, thrombocytes, on the wall of a vein. These thrombocytes, having become plastered together and fixed, build out into the stream a spongelike structure to which the white corpuscles adhere and in whose narrow interstices clotting *then* occurs. The process soon occludes the vein. The oldest portion, or head, of Zahn's classic thrombus is white and tough, since it consists mostly of platelets, and the neck, or mixed portion, which contains an increasing amount of fibrin and red cells, is dark red and still solid, but the tail, which is without plate-

let lamellae and which may extend for a long distance away from the neck, is necessarily clotlike and unsubstantial. Should it grow into a current, it may become so soft and flimsy that finally it can hardly be distinguished from normal blood. Insofar as this friable portion builds itself away from the heart it merely blocks more and more of the peripheral venous tree, but if it grows toward the heart, unfixed in the vein and waving in the current of an entering branch, fragile and ready to break from the body, it is a potential embolus—a serious threat to life. The tendency of most thromboses in their heartward progress is to stop abruptly and heal when they meet a vigorous current, but to grow out into a feeble one as the *propagating thrombus* just described, ready to become a source of minor infarction or of fatal pulmonary embolism.

CAUSES OF THROMBOSIS

There is in the literature much tiresome discussion of the influences which lead to thrombosis in veins. I am reminded of the first medical paper to which I ever listened, in which the author, a medical student, showed that practically every abnormality or disease of the human body was a source of constipation. Nevertheless, among the countless reported causes of thrombosis there are

From the Surgical Clinic of the Peter Bent Brigham Hospital, Boston.
Read before the Boston Surgical Society, December 6, 1937, in connection with a demonstration by Dr. C. H. Best of Toronto of the use of heparin in preventing experimental thrombosis in animals, in preventing thrombosis in glass tubes, and in controlling postoperative thrombophlebitis in human beings. An account of this work by Dr. Best and his associates has already been published (Best C. H., Cowan C. and MacLean D. L. Heparin and formation of white thrombi. *Science* 85:338-339 1937).

*Clinical professor, Harvard Medical School, surgeon, Peter Bent Brigham Hospital.

a number of fairly recognizable influences that may be held responsible

Disorders of the Vein Wall In the case of severe local injury, sepsis or actual varicosity, such a basic disorder is clear enough. Thrombophlebitis of the sigmoid sinus in middle-ear disease and the phlebitis of varicose veins are familiar examples. But most thromboses occur in the absence of any such known influences. Aside from rheumatic changes in the vein wall, changes which I have known to be a cause of a very deceptive thrombosis and a fatal embolism, evidence of the significance of degenerative changes even in acute fevers is rather speculative. However, in phlegmasia alba dolens, perhaps the commonest of all thrombophlebitides, I have found, on several occasions, when exploring the pelvis, a remarkably acute nonsuppurative inflammation surrounding the external iliac artery and vein and extending down the great femoral vessels into the thigh. This change has given me the impression of being the cause not only of the venous thrombosis but of arterial spasm as well. I cannot account for this phenomenon, which Cruveilhier noticed many years ago, though it is tempting to lay it to a lymphangitis reaching the iliac lymphatics from the legs or pelvis, and since there is little evidence to show how often it is present, it had perhaps best be kept in mind for future investigation and not taken too seriously at the moment.

Possibly in considering the disorders of the vein wall the factor of age ought to be included. For though thrombophlebitis does occur in young adult life, especially as a complication of childbirth and abdominal operations, middle to advanced age—the years from forty-five to sixty-five—is most liable to it.

Disorders of the Blood Perhaps the most concrete disorder of the sort described is dehydration, such as may result from vomiting, diarrhea, hemorrhage, deprivation of fluids or sweating at the operating table. There is also the rather vague but obviously important influence of injury, in the form of crushes, fractures and, of course, surgical operations. The influence of trauma may be local, as when thrombosis occurs in the great veins of the calf or thigh on the side of a fracture, or general, as when a femoroiliac thrombosis follows an abdominal or thoracic operation or an injury. Again, its influence may be immediate, or perhaps remote and related to the atrophy of disuse.

Conceivably, thrombophilic changes in the blood are related to clotting rather than to thrombosis. Bancroft and his co-workers have established a 'clotting index,' particularly in some preoperative and postoperative states. They believe that by the

use of certain dietary and medicinal steps they not only can lower a high index but can actually diminish the incidence of thrombosis. However that may be, abnormal states of the blood are more easily corrected than are other supposed thrombophilic influences, and, whether chronic or acute, should be kept in mind.

Disorders of the Venous Return These are of the greatest interest. They may be due to general circulatory failure, to cardiac weakness plus venous stasis or to venous stasis alone. Since thrombosis is most apt to occur in a *slowed* current, they are obviously fundamental. A patient sitting up or reclining in bed subjects the return flow from the relaxed legs to a decided slowing. Increased abdominal tension, as in any state of gaseous distention, during pregnancy or parturition, or following abdominal operations, obviously aggravates this unfavorable influence. But the anatomic relations of the upper femoral and iliac veins are perhaps even more important. There are many entering vessels, as is shown in the sketch. These branches, together with the few large valves of the region, are believed to cause eddies which encourage the deposition of platelets. The hypogastric arteries cross the external iliac veins, and the right common iliac artery crosses the left common iliac vein. These relations impede the natural current, on the left more than on the right. There is also present, in the upper calf and popliteal space, an area somewhat like that of the groin where many currents meet, and where many obscure thromboses undoubtedly originate. Aschoff has discussed all these influences most interestingly.

To sum up the principal factors favoring thrombosis there are, first, inflammation of the vein wall, a factor of great potential importance, little understood as yet, and undoubtedly influenced by advancing years, secondly, changes in the blood itself, whether in the nature of depletion or related to the obscure influence of trauma, and thirdly, the slowing of the venous return from the legs, dependent upon confinement to bed and aggravated by increased abdominal tension. Such factors tend to cause thrombosis in certain especially susceptible vessels, notably the femoroiliac veins and those of the calf and popliteal space.

VARIETIES OF THROMBOPHLEBITIS

These I have fully described elsewhere, so that I shall merely comment upon their individual peculiarities.

Phlegmasia Alba Dolens, Femoroiliac Thrombophlebitis, or Milk-Leg This very common form commences in the upper femoral and external iliac

vein. It leads to edema of the entire limb, but doubtless the severity and duration of the swelling depend on the amount of the venous tree occluded. It must be supposed that the less extensive the thrombosis, the more quickly and completely will

ly, to be sure—during active life. Moreover, it now seems probable that thrombosis begins much nearer the time of the operation, childbirth, injury or confinement to bed than was formerly supposed, that is, instead of coming on ten days or two weeks afterward, it is more nearly simultaneous with the onset of the exciting factor. Recently a patient of mine died of embolism from a femoroiliac thrombosis* on the day after an abdominoperineal operation, and there was suggestive evidence that the embolism actually occurred while he was still on the operating table. Possibly the time required for the initial thrombosis to lead to an extensive and obvious venous occlusion is longer than has heretofore seemed likely. Probably this time is decidedly variable. One can say definitely that when the entire leg is edematous, a fully developed femoroiliac thrombosis is present. But the absence of swelling does not rule out thrombosis.

One particularly interesting feature is the variation in the position and severity of the initial pain. It is sometimes severe enough to suggest serious arterial ischemia, a state which is even more definitely indicated when the arterial pulses in the foot become feeble or disappear. Such a state supports the hypothesis of a perivascular inflammation in the etiology of the disease. And of course a moderate fever and elevation of the pulse rate are very common.

Once a thrombophlebitis is established, the patient seems to become as it were thrombophilic. The other leg is involved far oftener than is generally supposed, but perhaps with so little swelling that the second process is overlooked. Occasionally a thrombophlebitis passes back and forth, recurring in the leg first attacked. Aschoff indicates that in a bilateral process the thrombosis ascends on the left at least to the point where the hypogastric artery crosses the external iliac vein, but on the right only to the inguinal ligament.

As to treatment, it is enough to say that elevation of the lower limbs above the level of the body for the purpose of drainage is essential, and that the affected leg should not be immobilized but exercised gently at the earliest possible moment. The thrombosis ends proximally well within the pelvis. It is very unlikely that a propagating thrombus is present. If present, it will presumably become detached whether or not the patient remains quiet. If it is not present, the proximal end of the thrombus will probably be healed by exercise and an improved circulation. Once edema has disappeared, the use of the limb, first in an elevated

* A fresh thrombophlebitis was found at autopsy in the external iliac vein. The embolus need not necessarily have come from there. Neither leg was swelled.

The Veins of the Lower Extremities (anterior view, semidiagrammatic). The areas most liable to thrombosis are indicated by arrows. On the left, a thrombosis in two of the great plexuses of the calf has extended into the femoral vein as a long, propagating thrombus (reconstruction from an actual case of fatal pulmonary embolism). On the right, the thrombosis of phlegmasia alba dolens is represented as ending cleanly where the hypogastric artery crosses the external iliac vein, the peripheral extent of the process is intentionally left vague.

a collateral circulation be established, and the more widespread the thrombosis, the more serious and prolonged will be the obstruction. Edema rather than blueness seems to measure the severity of the process. It is beginning to appear that a deep femoral or iliac thrombosis may be present without swelling, and Barker has shown that it can even establish itself—though rare—

and then in a dependent position, may gradually be resumed. For some months a bandage or elastic stocking for the lower leg is often required.

Deep Peripheral Thrombophlebitis Thrombosis in the Calf Muscles This treacherous disease has been little described. Its anatomic features are illustrated on the left in the accompanying sketch. Some of the great plexuses among the muscles of the lower leg become thrombosed. A very extensive process causes swelling and perhaps cyanosis of the ankle, or even of the calf. But as a rule the disease is very silent. The exciting cause is usually some minor injury or strain of the lower leg or foot. Following this, there is a little soreness of the calf muscles on use, especially on going upstairs. The ankle swells slightly. Merely going to bed often causes all signs of the disease promptly to disappear. There is no tenderness and only perhaps a little soreness on stretching the Achilles tendon. As a rule, elevation causes the proximal end of the thrombotic process to heal, but occasionally on renewed use of the leg the whole picture reappears. This suggests extension of the thrombosis and the possibility that a propagating thrombus has formed. Indeed, it appears that embolism from such a disease is far commoner than from a femoriliac thrombosis, yet I cannot agree with Aschoff that an embolus long and large enough to cause death can come only from the femoral region.

Repeated examinations are required in order to determine the frequency with which thrombosis occurs in the deep veins of the lower leg. My impression is that it is much commoner than is generally supposed, that it almost never merges into a femoriliac thrombosis, and that it usually heals on proper treatment, but that it is a relatively common source of pulmonary embolism. How often the femoral vein should be divided to forestall such an accident, I have no means of knowing, probably only when elevation is not followed by the permanent relief of symptoms*. Elevation is best obtained by raising the foot of the bed 15 cm and placing the unbandaged leg on a soft pillow. After ten days or so the leg is exercised freely in bed, and a semielastic bandage is used as life in the upright position is gradually resumed.

Superficial Thrombophlebitis in Non-Varicose Veins This is a freakish disease, which includes phlebitis migrans. A tendency to superficial thrombosis is perhaps familial, and some individuals are subject to recurrent attacks. Like other forms, it is decidedly common in the legs. A migrating

phlebitis is oftenest seen in those suffering from thromboangitis obliterans. Injuries and perhaps exposure to cold seem to be exciting causes of the more definitely localized processes. Such as these are obstinate in resolving, and tend to spread if the patient leads an active life or remains sitting up in bed. They disappear rapidly on elevation. For those which occur at or above the knee, high division of the great saphenous vein may usefully be combined with elevation. Fatal embolism is rare, but pulmonary infarctions occasionally occur.

Thrombophlebitis in Varicose Veins This is the least obscure and least interesting of the thromboses. The wall of the varicose vein is fibrosed and badly nourished. Very often its intima is cracked by unusual strains. Even without one's invoking the presence of infection in tissues of lowered resistance, there is sufficient reason for a considerable incidence of thrombosis in varix. That high pressures in the standing position are the usual cause of thrombosis in the slowed or reversed current is sufficiently proved by the fact that a varicose thrombosis is common in those who are active but rare in the bedridden. Once started in some pocket or distended area of a varicose vein, the thrombosis progresses until it meets a vigorous current. Thus it often reaches the femoral vein, which, however, it does not enter. Nor is embolism any but a rare occurrence. Infarctions I have seen, but not one fatal embolism.

Treatment of thrombosis in a varicose vein virtually ignores the possible detachment of an embolus. If the thrombosis is localized in the calf, an elastoplast bandage can be applied, and the patient allowed to go about his business. It is astonishing how rapidly under these conditions a cure occurs. If the process has reached the groin, elevation of the leg, as in other thromboses, is effectual. On the other hand, if high division of the saphenous vein above the thrombosed area can be accomplished, the immediate cure is more rapid and a recurrence is forestalled.

DISCUSSION

I have briefly discussed the treatment of the various sorts of thrombophlebitis in order to emphasize my conviction that thrombosis is encouraged to spread by slowing of the current of blood in and near the thrombosed vein, and is checked and healed when a vigorous venous return is created in the diseased part. In the vital matter of prevention, it would be ridiculous not to carry this conviction into action. I have noticed with interest and pleasure that one of my colleagues, with whom I have discussed the high incidence of pulmonary embolism following prostatectomy, is elevating the

*Femoral division below the profunda femoris, promptly performed would insure against embolism in all cases. So far as the venous circulation is concerned, the operation is harmless. Shall it be carried out in ten cases to save one or two?

foot of the bed following this operation. His practice is to raise it 15 cm for at least one half of each twenty-four hours. There is thus no bending at the groin and the feet are raised above the thorax. An extra pillow under the neck and head is of course allowed. That a similar course can be usefully followed in the pelvic surgery of women is proved by a recent publication of Schmid. In a series of 500 cases he shows that when postoperative elevation (25 cm) of the foot of the bed was used, thrombosis and fatal embolism disappeared, as against an expected incidence of from 12 to 23 thromboses and from 2 to 7 embolisms when a similar number of patients are kept flat in bed or allowed to recline. Indeed, no *reclining* during life in bed has been allowed in the present series. Routine precautions previously devised were naturally continued.

Now, in the attempt to forestall postoperative thrombosis, measures directed against dehydration and increased abdominal tension are common-sense precautions, if preferred, Bancroft's dietary regime and sodium thiosulfate to correct a high clotting index can be used. But is it advisable to keep patients subjected to upper abdominal operations, to say nothing of those having weak hearts and failing circulation, for long periods with their feet higher than their heads? Probably not, but perhaps for short ones—say from two to six hours in every twenty-four. Even a little help for the venous return is worth while. There is a tendency nowadays to work the modern adjustable bed to extremes, and to overemphasize the advantages of the half-sitting posture. This may partly account for what seems to be an increased incidence of thrombosis in the lower limbs.

As to the period at which preventive measures are most needed, I have already suggested that thrombosis follows more closely upon the exciting factor of trauma than has been generally believed. Best and his associates, in testing the effect of purified heparin on human beings, start its administration only an hour or two after operation. A similar course is being followed by Crafoord, of Stockholm. He first gives heparin three hours postoperatively and continues its use for four days. The period covered seems to me the one during which thrombosis is most likely to begin.

The treatment of established thrombosis, in order to be consistent with the foregoing conception of its onset and progress, must hurry the return of blood from the lower limbs and pelvis. Thus it should include especially elevating* the foot of the bed and abolishing the reclining position still so often used, applying heat rather than cold (I

have seen frostbites from the application of ice bags!), and permitting a reasonable freedom of motion rather than immobilization. If this kind of treatment appears to ignore the danger of embolism, the reason is plain enough. The only sure proof that a propagating thrombus, threatening fatal embolism, is present, is the onset of pulmonary infarctions. If such occur, an attempt to divide the vein proximal to the waving, fragile thrombus is in order. But if, as is usually the case, the dangerous propagating thrombus is silent until its fatal detachment takes place, I submit that rather than attempt to prevent this detachment by immobilization—which of course is futile, since even the patient's use of the bedpan is an athletic feat—the influences most likely to prevent its *formation* should be tried, namely elevation and mobility, or at least absence of immobility. It is not the turning over in bed that causes the fatal embolism, but rather the creation of a propagating thrombus in the slowed venous current which happened many hours, or more likely many days, previously.

A few words on the relation to pulmonary embolism of thromboses about the prostate, particularly in elderly men, and about the uterus and vagina should be mentioned. Such thromboses are probably common, and have often been shown to progress into the iliac vein, where they are a cause of phlegmasia alba dolens. In this form they are very unlikely to be a source of embolism. The question is rather whether they may, from a small and perhaps undetectable beginning, become the insecure anchoring point for a propagating thrombus which occludes no large vein but which floats through the hypogastric into the common iliac vein and is detached nearly or entirely in toto. Vain searches at autopsy for the source of long pulmonary emboli (from 25 to 30 cm) tempt one to say "Yes." Obviously more evidence is required. My own feeling has been that the popliteal region and upper calf are more likely to be the site of the long, folded thrombus such as is usually found fixed in the pulmonary artery in a fatal case of embolism. Even when autopsy reveals pronounced thrombosis in the veins of the pelvis, or perhaps the left external iliac vein, the source of embolus may still be an unnoticed process in one of the great plexuses of the calf. Such considerations suggest that more embolism occurs from undiagnosed than from evident, established thromboses.

* * *

I have taken the attitude that thrombophlebitis results from a combination of several factors, among which a slowed current, trauma and certain anatomic relations are pre-eminent. I have

*The treatment of a local varicose thrombosis by an elastic bandage and full use secures an active venous return without elevation.

ignored in the discussion of both etiology and treatment the possibility that the thrombocyte may be restrained by chemical means from throwing himself down to die in tempting locations. I am sure that since Best and his associates in Toronto have taken up the problem of forestalling thrombosis and even treating its established forms by the use of purified, nontoxic solutions of heparin, you will hear encouraging accounts of investigations along this line. Whether or not these prove fruitful, there is no harm in keeping in mind the fundamental principles relating to the etiology, progress and treatment of thrombosis.

BENIGN STRICTURE OF THE ESOPHAGUS COMPLICATING DUODENAL ULCER

EDWARD B. BENEDICT, M.D.,* AND ERNEST M. DALAND, M.D.†

BOSTON

ESOPHAGEAL stenosis is a rare complication of duodenal ulcer. Our purpose in reporting the following case is to call attention to this complication, and to emphasize the importance of treatment by esophagoscopy under local anesthesia, with bouginage by direct vision.

CASE REPORT

R. T. (U 22312), a 56-year-old, native-born clerk, first entered the Baker Memorial Hospital on February 16, 1937, complaining of epigastric pain and hematemesis. The pain was of 5 years' duration and was relieved by a bland diet and powders. The hematemesis was of a few days' duration 1 year previously, and of 5 days' duration at the present attack. Physical examination on admission showed a poorly developed, pale, emaciated man with dry skin and tongue. The blood pressure was 100/40. The red blood-cell count was 3,410,000, the hemoglobin 60 per cent, and the white-cell count 14,800. Two stool examinations were positive for occult blood. The patient was put on hourly feedings of milk and lime water, and a 500-cc. citrate transfusion was given. On this regime the bleeding stopped and the patient improved enough for x-ray examination 1 week after admission. The x-ray report by Dr. J. R. Lingley was as follows: "The esophagus appeared normal. The stomach showed generalized prominence of its rugae. The duodenum was constantly deformed. Projecting from the superior anterior margin of the cap there was a large, deep, penetrating ulcer crater." Re-examination 1 week later showed the ulcer to be smaller than formerly thought, measuring only 3 mm. in diameter. On March 4 the patient was discharged home relieved on a six meal, bland diet.

Because of a recurrence of vomiting the patient was readmitted on April 1, 1937. There had been no further

hematemesis, but the red-cell count was only 2,500,000, and the hemoglobin 50 per cent. Two transfusions were given. On April 6 he was still vomiting coffee ground material. On April 9 operation was performed by one of us (E. M. D.) and a gastric resection with posterior Polya anastomosis was done. Five days after operation there were some distress and gastric accumulation but no vomiting. A nasal tube was passed into the stomach twice a day for 4 days and then left in place for 2 days. A 500-cc. citrate transfusion was again given, and fluids were given intravenously. It was apparent that the stoma was not functioning as there was a daily increase in the gastric output. Twelve days after the gastric resection a second operation was done under local anesthesia. At operation the stoma was normal but there was a distinct kink in the distal loop of the jejunum. An enteroenterostomy was done, following which the patient made a rapid, uneventful convalescence, and was discharged home on May 8.

He was admitted for the third time on September 2, 1937. One week after arriving home, about 3½ months previously, the patient began to experience difficulty in swallowing semisolid foods, and limited his diet to egg-nogs and other liquids. He began to lose weight. One month prior to entry it became impossible for him to swallow anything except water and ginger ale. His weight on this admission was 93 lb., a loss of 37 lb. since his first admission 6 months previously, and a loss of 20 lb. in the past month. Physical examination showed an exceedingly dehydrated, emaciated man, retching and vomiting saliva. Constant intravenous fluids were begun at once. X-ray examination of the esophagus (Fig. 1) was reported as follows by Dr. Lingley: "Barium met almost complete obstruction in the lower third of the esophagus, where the lumen was reduced to a very fine tube for a distance of about 5 cm. The upper margin of the defect was cone shaped, and its lateral margins finely irregular. An ulcer crater, however, was not visualized and there was no filling defect suggestive of cancer. After 1 hour only a very small trace of barium had reached the stomach and the esophagus above the lesion was mod-

crately dilated. The findings are those of a stricture in the lower third of the esophagus, probably due to a benign peptic ulcer" (Plates taken on the first admission had shown a normal esophagus)

Esophagoscopy under local anesthesia was performed by one of us (E B B) on September 8. About 1 cm above the stricture there was marked reddening and inflammation of the esophagus. The opening of the stricture was almost obliterated. There was no evidence of ulcer or carcinoma. Under ocular guidance a No 8 French silk-woven esophageal bougie was directed into the lumen and

Figure 1. X-ray of the esophagus before treatment, showing almost complete obstruction in the lower third.

passed readily into the stomach. That the narrowing was due largely to esophagitis was soon evident, for once the lumen was established bougies up to No 16 French passed readily. Following this the patient was able to take small amounts of liquids by mouth. Two days later, esophagoscopy was repeated under local anesthesia, bouginage was carried out as before up to a No 16 French, and a soft duodenal tube (No 14 French) was introduced through the stricture into the stomach. Feedings were then given through the tube. Four days later esophagoscopy was again done under local anesthesia, bouginage was carried out up to a No 22 French, and a No 18 French duodenal tube was placed through the stricture. Intravenous fluids were discontinued and liquids, including beef juice, fruit juices and milk, were given through the tube. In spite of a low serum protein (4.9 gm. per cent), there was never any sign of nutritional edema. Three days later a fourth esophagoscopy was done as before, the esophagitis was found to be almost entirely healed, and the stricture was dilated to a No 24 French bougie. No feeding tube was placed and the patient began eating soft solids without difficulty. At two subse-

quent esophagoscopies on September 21 and September 27, a small (7 mm) esophagoscope was passed through the stricture into the stomach.* Following the last esophagoscopy a lumen was obtained which permitted a six meal bland diet of minced meat and strained vegetables. From then on convalescence was rapid, there was a gain in weight of 11 lb in the 22 days following the first esophagoscopy, and a marked gain in strength. The patient was allowed up and about the ward, and was discharged home on September 30, with instructions to return for further dilatation to maintain and increase the esophageal lumen. X-ray examination (Fig 2) at the time of discharge was reported by Dr Lingley as follows: "The stricture in the lower third of the esophagus has diminished in length and the lumen has definitely increased since the last observation. Barium now passes with only slight delay."

Esophageal stenosis as a complication of peptic ulcer of the stomach or duodenum has been reported by Vinson¹ and C. L. Jackson.² The co-existence of peptic ulcer of the esophagus and gastric or duodenal ulcer has also been reported (Abel,³ C. Jackson,⁴ and Friedenwald, Feldman

Figure 2. X-ray of the esophagus after treatment, showing free passage of barium through the stricture.

and Zinn⁵). In the case reported here no esophageal ulcer was demonstrable. In a study of 40 cases of cicatricial benign stricture of the esophagus of unknown origin Vinson reports 2 cases associated with duodenal ulcer. In C. L.

At the last examination a piece of tissue appeared to be lying free in the lumen of the esophagus at the site of the stricture. This was removed with forceps for pathological examination. The report was cellular exudate.

Jackson's report of 3 cases of esophageal stenosis associated with ulcer of the stomach and duodenum, 2 showed esophageal ulceration and 1 showed benign organic stenosis without peptic ulcer of the esophagus. The absence of substernal pain in our patient and the appearance of the esophagus by x-ray and by esophagoscopy make it probable that we were dealing with a benign cicatricial stenosis following acute esophagitis. Guisez,⁵ quoted by Friedenwald, Feldman and Zinn,⁶ is convinced that many of the so-called simple ulcers of the esophagus are actually only localized inflammatory processes which finally terminate in stenosis without undergoing definite ulceration. As to the cause of the esophagitis in this case and the few similar ones reported, vomiting or regurgitation of acid gastric secretions may be of importance. Infection of the esophagus from the gastric or duodenal ulcer either directly or through the lymphatics may be a factor. The general nutritional state of the patient may also play a part. Bartels,⁶ in a pathological and clinical study of 82 cases of acute ulcerative esophagitis, found gastric contents in the esophagus in all cases at necropsy. He did not discuss peptic ulcer of the esophagus, but esophagitis with phlegmonous or superficial ulcerations and erosions. In his opinion

It seems imperative that the action of the gastric juice be accepted as contributing to the lesion, because gastric juice was present uniformly in the lower third of the esophagus. Vomiting and even nausea without vomiting with relaxation of the cardiac spasm, seem extremely important as factors that permit gastric juice to come in contact with the esophagus. It seems necessary that the patient should be debilitated, but not necessarily dying before changes can occur in the esophagus. Debilitating and terminal states imply slowing of the circulation of the lower part of the esophagus, which normally is poor, and therefore loss of the normal resistance of esophageal tissue to trauma, and of its ability to regenerate.

In our patient vomiting was not a prominent symptom either before or after operation, although there were high jejunal obstruction, gastric distention, and probable regurgitation of gastric secre-

tions into the lower end of the esophagus. Debilitation, however, was very marked. As to the etiologic importance of an in-lying gastric catheter, we do not believe it to be a factor, as it is so commonly used before and after gastric surgery without untoward results. In this connection Bartels concluded that passage of a tube is not an etiologic factor and may only incidentally be an aggravating one.

Symptomatically such patients may exhibit gas, substernal or epigastric distress, heartburn, nausea, regurgitation or vomiting, but as the esophageal lumen becomes narrow the outstanding symptom is difficulty in swallowing solid foods, and later with almost complete stenosis there is regurgitation of liquids. The diagnosis is easily made by x-ray and esophagoscopy.

The treatment should be esophagoscopy under local anesthesia, with bouginage under direct vision through the esophagoscope. Local anesthesia is used because general anesthesia is not only unnecessary but also dangerous in debilitated patients. Bouginage should be carried out under ocular guidance through the esophagoscope because, as Jackson and Jackson⁷ have repeatedly emphasized, "blind bouginage should be discarded as an obsolete and very dangerous procedure."

SUMMARY

A case of benign stricture of the esophagus, probably due to an acute esophagitis following gastric resection for duodenal ulcer, is reported.

The etiology, symptomatology, diagnosis and treatment are briefly discussed.

HYPERVENTILATION TETANY

REED HARWOOD, M.D.*

BOSTON

PROLONGED hyperventilation, whether practiced voluntarily in the laboratory or occurring as the result of some pathologic state, produces certain physicochemical changes that lead to tetany. The earliest observations on this subject were made between 1908 and 1912, when Haldane and Poulton,¹ Henderson,² Edsall³ and others found that during experiments on hyperventilation their subjects complained of dizziness, tingling of the fingers and toes, and rigidity of the hands. In 1920, Collip and Backus⁴ and, independently, Grant and Goldman⁵ confirmed these findings and recognized the symptoms as those of tetany. Two years later, clinical reports of tetany caused by hyperventilation first appeared.⁶⁻⁷ Since that time there have been numerous case reports and considerable experimental work on the subject. In this paper the clinical syndrome will be discussed and some illustrative cases will be presented. But first it is necessary to outline the important chemical and physiologic changes produced by hyperventilation.

PHYSIOLOGY

Forced respiration causes a sharp drop in the carbon-dioxide tension of alveolar air.^{1,4,6} As a result, an increased amount of carbon dioxide is washed out of the blood, and there is a drop in the carbon-dioxide content of the plasma.^{4,6} An increase in the pH of the plasma and a state of alkalosis accompany this change. At the same time there is an increase in the pH of the urine and a suppression of the output of urinary ammonia. These alterations in acid-base equilibrium have been constantly recorded in investigations on hyperventilation. Numerous other changes have been reported. Some observers have noted a slight increase in the concentration of serum calcium,⁴ while others have noted no change.^{8,9} A marked drop in the concentration of serum inorganic phosphorus has been noted.⁸ Several investigators have observed a rise in concentration of blood chlorides,^{10,11} and others have noted a decreased concentration of blood sodium.¹² Acetone frequently appears in the urine.^{8,10} In one experiment¹³ a drop in cerebrospinal fluid calcium was reported, but this finding was not confirmed by other investigators.^{9,14}

In addition to the alterations in blood chemistry, various other phenomena have been observed. A

period of involuntary apnea² frequently follows a period of forced respiration. Breathing is not resumed until the level of plasma carbon dioxide has risen to the point where the respiratory center is stimulated. A diuresis often follows hyperventilation.⁴ There is usually noted a drop in systolic and diastolic blood pressures.¹⁵ The pulse rate is increased. Experiments on dogs indicate that there is no attendant depression of the circulation.¹⁶ The changes in the electrocardiogram are very slight; most observers report that the R waves and T waves have a smaller amplitude during forced breathing.¹⁷ Several phenomena appear which are common to this and other types of tetany. There is an increased electrical excitability of peripheral nerves.¹⁸ Chvostek's sign and Trousseau's sign are regularly present.

Although it is not my purpose to discuss the pathogenesis of hyperventilation tetany, some comment on the blood chemistry is pertinent from the therapeutic standpoint. Attacks of this type of tetany can be stopped by the administration of 5 per cent carbon-dioxide inhalations, by re-breathing and by the patient's holding his breath. All these have the effect of raising the carbon dioxide content of the plasma, and thus simply reverse the changes produced by hyperventilation. Similarly, the administration of ammonium chloride, which decreases the pH of the blood without necessarily altering the carbon-dioxide content, tends to prevent hyperventilation tetany. Finally, attacks of this type of tetany have been immediately aborted by the intravenous injection of a calcium salt more alkaline than the blood.¹³ It is thus possible that the decreased carbon-dioxide content and the increased pH of the plasma in hyperventilation produce some change in the blood calcium which causes tetany.

CLINICAL CONSIDERATIONS

Hyperventilation is seen in a wide variety of clinical conditions. Among the neurologic disorders it is seen most frequently in encephalitis lethargica.⁶ Hyperventilation is not an uncommon response to pain,⁷ and is occasionally seen during ether anesthesia.¹⁹ Shannon²⁰ has produced evidence that, in certain cases, tetany of the newborn is due to hyperventilation. In cases of alkalosis of other origin, a slight amount of hyperventilation may precipitate an attack of tetany.¹¹

Hyperventilation tetany is frequently seen in

From the Medical Department of the Massachusetts General Hospital, Boston.

*Assistant in medicine, Massachusetts General Hospital.

pregnant women²¹ In this connection it is interesting to note that there is normally an increased pulmonary ventilation and a decreased carbon-dioxide content of the plasma during pregnancy. However, the casual relation of these facts has not been definitely established.²²⁻²³

By far the largest number of reported cases of hyperventilation fall in the group of psychoneuroses. Of these, anxiety neurosis and hysteria²⁴ appear to be the commonest, but hyperventilation is also a frequent response to rage, sorrow, fatigue, excitement and apprehension. Tetany has occurred during operations under local anesthesia,²⁵ after attacks of asthma²⁶ and after athletic events.⁹ A more complete review of the literature would doubtless disclose many other factors which have precipitated tetany. The references cited here are given merely to show how frequently and under what varied circumstances hyperventilation and tetany may occur.

SYMPTOMATOLOGY

There is considerable variation in the symptoms reported by patients and laboratory workers suffering from hyperventilation tetany. Most patients complain first of dizziness, accompanied by numbness and tingling of the fingers and toes. Blurring of vision and tightness in the throat are frequently noted. There may follow difficulty in speaking, tightness across the upper chest or over the precordium, and spasm of the hands and feet. Twitching of the facial muscles may also occur. In very severe cases laryngeal stridor, generalized convulsions, opisthotonos and unconsciousness may occur. Usually, however, the tetany does not progress beyond the point where spasm of the hands appears. In many cases malaise, weakness and helplessness are prominent features. The patient falls to the ground as if in a faint, but consciousness is clouded little or not at all. Occasionally the patient becomes very frightened and has a feeling of impending death. Some patients learn from oft-repeated attacks that there is nothing to fear.

In any individual case, it will be found that many of the symptoms outlined above are not present, but almost without exception numbness and tingling and a certain amount of malaise or dizziness are present. Attacks vary greatly in duration, lasting from a few minutes to several hours. As the symptoms subside, the patient notices a physical and nervous fatigue which is proportional to the severity of the attack, and which may last for several days.

DIAGNOSIS

The diagnosis is not difficult. In most cases the increased rate or depth of respiration is obvious.

There is a striking absence of the signs of cardiac or pulmonary disease. Chvostek's sign and Trousseau's sign are present, and the patient may exhibit typical carpopedal spasm. In certain cases, however, the hyperventilation is not at all obvious. A patient may have very slightly increased ventilation over a long period of time, and develop tetany without any marked increase in respiration. Or a patient may not be observed until the attack is subsiding and hyperventilation has ceased. In either of these cases a diagnosis of hyperventilation tetany may be confirmed by asking the patient to overbreathe vigorously for a few minutes. The patient reports a rapid return of symptoms identical with the symptoms of the attack, and the signs of tetany become apparent much sooner than would be expected in a person whose acid-base balance had not previously been disturbed. This test is quite harmless. Besides establishing the diagnosis, it is a dramatic way of pointing out to the patient the source of his trouble.

Several other conditions should be excluded. In the first place, tetany due to low serum calcium is to be considered. If the serum calcium is normal, tetany due to rickets, osteomalacia, hypoparathyroidism, steatorrhea and renal failure may be ruled out. Secondly, alkalosis from other causes should be considered, since tetany may occur after repeated vomiting and after excessive ingestion of alkalis. Finally, the possibility that the hyperventilation is due to a lesion in the brain must be recognized.

CASE REPORTS

Case 1 (M. G. H. No. 341569) R. P., a 21-year-old, single, white woman, was admitted to the hospital in October, 1934, complaining of intermittent attacks of weakness and collapse. She had been perfectly well until 1931, when she had had her first attack. This started suddenly, with dizziness, blurring of vision and frontal headache. She felt weak in the arms and legs, and noted numbness and tingling in the fingers and toes. The weakness progressed until, no longer able to stand, she fell to the ground crying uncontrollably. She remained fully conscious, but found that she was unable to speak, attempts to do so bringing forth only unintelligible sounds. Gradually her symptoms subsided, her vision cleared, and the numbness and tingling disappeared. She remained weak for several hours, and complained of extreme muscular fatigue.

After this first episode, the patient had similar attacks at irregular intervals, varying from 2 weeks to 3 months. The duration of attacks ranged from 10 minutes to 1½ hours. Attacks usually occurred at times of excitement or during emotional upsets. On two occasions the patient collapsed while swimming. At no time was there any loss of consciousness, convulsions or incontinence. Between attacks she felt well, and there were no other symptoms. Her past history and family history were negative.

Physical examination was essentially normal. The blood pressure was 132/88. A neurological examination was negative. Routine examinations of the blood and urine were within normal limits. The spinal fluid contained

50 red blood cells per cu mm and a protein of 51 mg per cent. The basal metabolic rate was -4 per cent. X ray of the skull was negative

The patient had an attack a few minutes after the metabolism test was completed. She complained of weakness, malaise and tingling in the fingers and toes. She began crying in a hysterical fashion and was soon unable to speak, although she was able to understand questions and to answer by shaking her head or nodding. During this attack her color was good. She was very restless, and threw herself about on the bed, crying constantly. Her respirations were markedly increased. The blood pressure was 160/110, and the pulse 90. Chvostek's sign was present, and Trousseau's sign was elicited 20 seconds after applying the tourniquet. The patient's condition remained unchanged for 30 minutes. At the end of this time venous blood was removed for analysis, and she was given 10 cc. of a 10 per cent solution of calcium gluconate intravenously. She experienced immediate symptomatic relief. The venous blood sugar was 101 mg per cent. The serum calcium was 11.0 mg, and the serum phosphorus 2.2 mg per cent. On the following day the serum calcium was 10.2 mg, and the phosphorus 4.0 mg per cent.

Further studies on this patient revealed that she reacted to any emotional situation by increased rate and depth of respiration. Excitement of any sort, pleasant or otherwise, provoked the response of hyperventilation. Except for this type of response and a tendency to become easily excited, she appeared well balanced. She gave the impression of being genuinely eager to be cured.

The treatment consisted simply of an explanation of the mechanism of her attacks. To illustrate the validity of this explanation she was asked to breathe rapidly for a short period. A typical attack was thus induced in 6 minutes. A paper bag was then placed over her head and secured loosely about the neck. She continued to breathe rapidly, but her symptoms subsided in a few minutes.

The patient was discharged with instructions to observe and control her breathing, especially in moments of stress, and to hold her breath or rebreath into a paper bag if an attack occurred. Three years later (October, 1937) she wrote to say that she had had no further severe attacks. She had continued to have occasional tingling of the hands, but had been able to prevent the development of further symptoms by holding her breath.

Case 2.* Mrs. J. W., a 54-year-old housewife, had suffered from intermittent attacks of collapse since the age of 23. These attacks varied greatly in duration and intensity, but a typical seizure was as follows. There was a sudden onset of extreme fatigue and depression, and the patient felt like lying down at once. This was quickly followed by blurring of vision, and numbness and tingling of the hands and feet. A sudden weakness of the legs caused her to collapse on the floor, where she lay fully conscious but unable to move or speak. At the same time she noted a sense of pressure on the upper part of her chest, and complained of a smothering sensation which caused her to gasp. As the symptoms subsided she felt little desire to breathe at all. After the attack the patient felt very weak, and was quite fatigued for several days.

Similar attacks occurred on an average of every 3 months, although occasionally the patient was symptom-free for nearly a year. Recently attacks had become increasingly frequent and severe, and varied in duration from 30 minutes to 5 hours. On one occasion a doctor observed spasm of the hands. It was frequently noted

that her pulse was feeble and her breathing was irregular. At the height of one attack her respirations ceased altogether for several minutes. When her symptoms were particularly severe she appeared to be "practically unconscious," and retained only a vague recollection of the episode. On several occasions a marked diuresis followed an attack.

The family history and past history were negative. At the age of 28 a cholecystectomy was performed. At 33 a small uterine fibroid and the appendix were removed. After this operation the surgeon told her that she had taken the ether "very badly" and warned her against further anesthesia.

Between attacks the patient enjoyed robust good health. She played golf regularly and was active in social affairs. Her obvious well being in these intervals, coupled with the apparent seriousness of her attacks, puzzled her physicians. The patient noted that her attacks always followed a period of unusual activity or emotional stress, it was when her social calendar had been particularly full that she succumbed. She gave the impression of being calm, well adjusted and energetic.

On April 28, 1936, the patient had a typical attack in my office. Suddenly complaining of dizziness and tingling of the hands, she threw herself on the couch as though completely exhausted. Her color was good. She was breathing deeply at the rate of 30 respirations per minute. The pulse was 90 and of good quality. The blood pressure was 140/90. The heart sounds were normal, and the lungs were clear. Chvostek's sign was present, and Trousseau's sign was elicited in 40 seconds. The patient was instructed to hold her breath. She did this for 2 minutes without apparent difficulty and noted that her symptoms abated considerably. She was then asked to breathe rapidly. Her symptoms quickly returned, but again subsided after a paper bag had been placed over her head.

On the following day she still complained of fatigue, but had no other symptom. The blood sugar was 103 mg per cent, and the serum calcium 9.7 mg. She was discharged with instructions for regulating her breathing. For 18 months she had no severe attack, although occasionally the warning symptoms of fatigue and blurring of vision occurred. In October, 1937, she had a fairly severe attack, following several weeks of overactivity and nervous strain.

Cases 1 and 2 are nearly identical in that hyperventilation was a constant and unconscious response to emotional stimuli and fatigue. Severe attacks of collapse occurred irregularly over a period of years, and interfered to a considerable extent with activity. In neither case was there an obvious neurotic background to the overbreathing. In Case 1 the attacks ceased when the method of preventing them had been explained to the patient. In Case 2 there was only one severe attack in the subsequent eighteen months. It is apparent, however, that neither patient became sufficiently aware of the importance of hyperventilation. The transient episodes of dizziness and tingling of the extremities, occurring under circumstances that previously had preceded a major attack, indicated that these patients continued to respond to certain situations by overbreathing.

*The author is indebted to Dr. Roy R. Wheeler for permission to publish the report of this case.

Case 3 (M. G. H. No. 55942) N. F., a 17-year-old boy, was referred to the Out Patient Department of the Massachusetts General Hospital with a diagnosis of tetany due to overventilation. Six months before admission he began having attacks of severe precordial pain accompanied by dizziness, sweating, numbness and tingling of the hands, spasm of the hands, twitching of the face and shortness of breath. The attacks lasted from 30 minutes to 2 hours, and left him with a sense of extreme weakness and fatigue. Attacks occurred almost daily, and were of such severity that his doctor advised complete bed rest. His attacks continued unabated. The patient developed a constant precordial ache, which became a sharp constricting pain during the attacks of spasm. Temporary relief was afforded by the intravenous injection of a solution of calcium levulinate. Later the patient was given calcium salts and ammonium chloride by mouth, and spasm of the hands no longer occurred during attacks. Otherwise his condition remained unchanged.

The family history and past history were negative. At physical examination the patient was well developed and appeared healthy. He was extremely nervous and tense, and was unable to sit quietly. He was breathing deeply and rapidly, because he felt short of breath, unable to get a deep breath. The heart and lungs were normal. The blood pressure was 160/80. The pulse was 120. The knee jerks were hyperactive. Chvostek's sign was present, and Trousseau's sign was quickly obtained. The urine was neutral to litmus, and normal in other respects. The serum calcium was 11.0 mg per cent, and the serum phosphorus 2.42 mg. A blood Hinton test was negative.

The patient was asked to omit all medication and was given an explanation of his symptoms. He was advised to stop trying to get a deep breath, and to control his breathing at all times. One week later he returned to the clinic, and presented an entirely different appearance. He was calm and quiet. His blood pressure was 110/70. The pulse was 80. The tendon reflexes were normal. The signs of Chvostek and Trousseau could not be elicited. The patient had had no further attacks, and there had been no precordial ache. He stated that he had had no difficulty in controlling his breathing. In a letter 6 months later (November, 1937) the patient reported that he was still nervous at times, and suffered occasionally from shortness of breath, precordial pain and weakness. He had had no further attacks of carpal spasm.

The precipitating factor in this illness was a difficult family situation which apparently kept the patient in a state of tension that was reflected in his overbreathing. Anxiety about his condition and the precordial ache doubtless served to increase his hyperventilation once the state of tetany had been established. Although he derived some benefit from his visit to the clinic, his later course was determined more by his emotional conflict. In this case, as in Cases 1 and 2, the habit of overbreathing persisted, but was not so excessive as it had been. If these patients had been available for a thorough psychiatric investigation a more permanent and complete improvement might have been obtained.

In view of the variety of conditions in which hyperventilation tetany can occur, it is probable that it is much commoner than is indicated by a

survey of the literature. That 2 of the cases reported above went undiagnosed for years is certainly an indication that the condition is not sufficiently understood by the practicing physician. The presence of carpal spasm undoubtedly points the way to a correct diagnosis in a large majority of cases. But in many instances, as shown in the 3 cases reported in this paper, incapacitating symptoms may develop in the absence of carpal spasm. Transient episodes of tingling of the extremities with a vague history of periodic attacks of collapse or "hysteria" should direct the physician's attention toward the possibility of hyperventilation. If an effort is made to see the patient during an attack, this possibility can be affirmed by the presence of the signs of tetany. Once the diagnosis has been made, it is possible to give the patient instruction in regard to proper breathing. In many instances he will learn to prevent the occurrence of further attacks.

SUMMARY

- 1 The chemical and physical changes occurring in hyperventilation tetany are briefly reviewed.
- 2 The clinical aspects of this condition are discussed.
- 3 Three cases in which frequent attacks of tetany resulted from overbreathing are presented. In each case, improvement resulted when the mechanism of the attacks had been explained but the patients continued to respond to certain situations by increased ventilation.

TRACY B. MALLORY, M.D., *Editor*

CASE 24141

PRESENTATION OF CASE

A sixty-four-year-old, white, Italian barber entered the hospital with the complaints of anorexia and vomiting of two months' duration.

For twenty-five to thirty years before entry he had always had a poor appetite, and for the fifteen years before entry had had frequent attacks of nausea and vomiting. He was bothered greatly by gaseous distention and "gas pains," which came on directly after eating and were usually relieved by eructations. However, he frequently became nauseated and regurgitated or vomited the food he had eaten. The frequency of vomiting could not be determined, but it usually occurred after eating large amounts of food. Soda gave him no relief. He never vomited fresh or changed blood or passed tarry stools. For many years his bowels had been sluggish, and it had been necessary for him to take castor oil or other laxatives two or three times a week. If he did not take laxatives, his vomiting occurred more often.

About two months before entry he developed a dull, gnawing, aching sensation in his midepigastrium, which came on ten minutes to one and a half hours after eating and was usually relieved by vomiting. The aching sensation often radiated into both upper quadrants and occasionally through to the back. Gradually the vomiting changed to frank regurgitation of practically everything eaten or drunk. He was able to swallow successfully but could not lie down after meals because the food would "roll right out," practically in an unchanged state. During the two months before entry he had lost 22 lb and had become very weak and pale.

For fifteen or twenty years before entry he had had a chronic cough productive of moderate amounts of yellowish sputum. Most of the sputum was raised in the morning. It was never foul or blood streaked. For two or three years before entry he had a sensation of a "little ball" tickling the back of his throat. He had had no night sweats or persistent fever. His past history was otherwise essentially negative, and his family history was not contributory.

Physical examination revealed a fairly well-developed man, showing evidence of considerable weight

loss. The skin and mucous membranes were pale, and the tongue was heavily coated. The heart was negative, and the blood pressure was 110 systolic, 75 diastolic. At the right lung base posteriorly there were slight dullness and decreased tactile fremitus, voice sounds and breath sounds. Coarse rhonchi were heard in the right chest, which disappeared on coughing. There was an indefinite hard tender mass in the epigastrium just beneath the xiphoid, which was difficult to delineate because of spasm of the abdominal muscles. The mass seemed to extend into the right upper quadrant, and was thought possibly to be continuous with the liver. No definite liver edge could be felt and no other masses or spasm were made out. The rectal examination was negative.

The temperature was 97.5°F., the pulse 65. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,500,000 with 65 per cent hemoglobin, and a white-cell count of 31,500 with 88 per cent polymorphonuclears. The sputum was yellowish in color and contained gram-positive diplococci. The vomitus contained particles of food and gave a negative guaiac test. Gastric lavage was attempted, and the fluid obtained contained no free or combined hydrochloric acid and gave a 2+ guaiac test. The blood Hinton and a 1:40,000 tuberculin test were negative. The non-protein nitrogen of the blood was 45 mg per cent.

Fluoroscopic x-ray examination of the chest revealed a large mass projecting to the right from the upper mediastinum. The lung fields were otherwise clear, and the diaphragm appeared normal. Barium given by mouth filled a tremendously dilated esophagus, and the previously observed mass was seen to represent the esophagus almost filling the right upper chest. The dilatation was greatest in the upper portion of the esophagus but was also marked throughout the lower half. No barium passed into the stomach during fifteen minutes of fluoroscopic examination.

On the day following entry his temperature rose to 100°F and on the next day to 102°F. His respiratory rate increased to 35. Thorough lavage of the esophagus was done on several occasions and somewhat improved his condition. However, only very small amounts of fluid could get through the cardia. His temperature and respirations remained elevated, and on the sixth day definite signs of pneumonia could be made out at the right lung base. He died on the eighth day.

DIFFERENTIAL DIAGNOSIS

DR. CHESTER M. JONES. The story seems to me to present two possible diagnostic problems in addition to the obvious terminal pneumonia. In the first place we have a patient who has had for at

least fifteen years, and possibly twice that length of time, symptoms of esophageal obstruction with gradually increasing obstruction and gradual enlargement in the size of the esophagus. Anything that extends over such a period of time by itself cannot be considered a malignant lesion. Therefore, I should say that the symptoms and story were those of a benign obstructing lesion at the lower end of the esophagus. The x-rays show an enormous barium-filled tube that narrowed down in a funnel-shaped manner to the cardiac orifice. There is no mention in the x-ray report in the record that there is anything but a symmetrical or fusiform narrowing of the lower end of the esophagus. The mass that was first noted by x-ray might have been outside the esophagus or connected to it by a small opening. In other words, it might be a huge esophageal diverticulum under the right clavicle, filled with food and fluid, but it seems more reasonable to assume that the whole picture represents a tremendously enlarged esophagus. It is still possible that there was a diverticulum of the upper third, as a matter of fact the upper third is the weakest portion and does dilate readily if back pressure is put against it. So the x-ray findings fit perfectly well with an obstruction at the lower end of the esophagus and explain part of the clinical picture. I cannot conceive of this obstruction's having been due primarily to cancer at the cardiac end of the esophagus. Fifteen years of continuous symptoms without change in character would seem to indicate a benign process which was gradually increasing.

I suppose it is possible that this process could be a stricture due to previous trauma or to chemical injury following the ingestion of lye. It could be due to congenital narrowing of the lower end of the esophagus or a congenital hypertrophy of the cardiac end of the esophagus. These conditions do occur. We have seen as large an esophagus as this due to cardiospasm of many years' duration. I can recall one that had a story of at least twenty years' duration with a very large esophagus. They do not mention the actual content. I think the largest amount recorded is 1800 or 2000 cc. So far as the size of the dilated esophagus is concerned, any of these benign processes are possible causes, but they will not explain certain other findings. Obviously the man is dehydrated, undernourished and constipated because of lack of sufficient food. He is anemic because of malnutrition. His nonprotein nitrogen is elevated because of dehydration. The only unexplained laboratory finding is the leukocytosis of 31,000 with 88 per cent polymorphonuclears. That goes perfectly well with a pneumonic infection which is

not obvious on these plates but is suggested by the admission chest signs, and we know that he subsequently died with a clinical picture of pneumonia.

We are left with a story of chronic cough and yellow sputum. He may have had bronchiectasis, but the x-ray findings do not suggest any such possibility. This chest plate is an oblique view. It does not suggest a bronchiectatic process to me, nor does it suggest any real pneumonic process. I am not going to consider the story of cough and sputum as related to the main part of the history.

Two months before entry he gives a story of something new—epigastric pain coming ten minutes to one and a half hours after meals, usually relieved by vomiting. Here again we may be dealing with an overdilated esophagus with a certain amount of irritation at the lower end which is relieved by regurgitation. This symptom, however, seems to have a different significance from that of the earlier symptoms.

We have a physical finding which I think is extremely important, that is, an indefinite, hard, tender mass in the epigastrium just below the tip of the xiphoid. That does not go with esophageal disease unless it represents metastases from tumor. I have not seen a sufficient number of cases of cancer of the esophagus to know where they tend to metastasize. I should expect them to metastasize to the mediastinal nodes rather than below the diaphragm. The mass may be associated with the liver, of course, or it may be the stomach, but it has to be one of these organs.

It is entirely possible that we have to make two diagnoses, one of a benign process which is more or less obstructing the esophagus and has done so increasingly over a period of many years, and then a second process which has changed the symptoms recently and at entry is associated with a mass at the tip of the xiphoid. It may represent cancer of the stomach or just outside the stomach and in the liver. I do not believe he has tuberculosis, but the negative 140,000 tuberculin test does not rule it in or out. It is of some interest that the Hinton test is negative. It says here "only very small amounts of fluid could get through the cardia." I do not feel at all sure that they knew where the tube was. It is possible it never went below the cardia, and it is also possible that they never entirely emptied the esophagus. I am wondering about the possibility of prolonged irritation at the lower end with possibly an inflammatory process with erosion and ulceration and an abscess below it, which might be the basis of this epigastric mass. The mass is tender, which is not like many malignant processes, but the patient did not come in with

the clinical signs of abscess formation. In other words, he did not come in with high temperature although he did have a leukocytosis. I think it is more logical to interpret the leukocytosis as going with something that is beginning to form in the right chest that subsequently became pneumonia. I am disturbed that there is nothing in the x-ray films interpreted as a pneumonic process at the right base, nevertheless, I believe he died of a terminal pneumonia. I am sure he had a stricture of the esophagus due to a very benign process. I do not believe it was due to esophageal ulcer, because he does not give a story of ulcer pain. I do not believe he has cancer of the esophagus as an explanation of the entire picture. The recent picture, plus the epigastric mass, I am inclined to explain on the basis of cancer. A malignant tumor in the stomach would be my first guess.

DR. FRANCIS M. RACKEMANN: Do you suppose he could have a rupture at the lower end, with abscess formation?

DR. JONES: I mentioned that as a possibility. Of course if it involved that portion under the diaphragm he could get a localized abscess. I think that is a possibility.

DR. JAMES H. MEANS: Would ventral hernia give a picture like this, with recent cardiospasm at the upper end of the stomach?

DR. AUBREY O. HAMPTON: This picture of the esophagus, the extreme dilatation and this spasm, is quite consistent with cardiospasm. The difficulty of ruling out any other lesion would be great because his esophagus is filled with food and these filling defects cannot be displaced by palpation or any other maneuver except lavage, and it apparently was not done during this examination. He did show this defect in the anterior aspect of the lower end of the esophagus which is present when he is lying down or standing. It does not materially shift or change. It is also strange that this portion of the esophagus is much smaller than the upper portion. I think that the peristaltic activity in the posterior aspect of the esophagus is more than you would expect in the presence of cardiospasm alone, and, furthermore, we do not see the same peristaltic waves in front. I do not see any evidence of perforation of the esophagus or of pneumonia. The diaphragm is perfectly normal in outline and position.

DR. JONES: That was one thing I should have mentioned. If he had a perforation of the esophagus that caused a mass below the xiphoid you should have been able to see barium going through.

DR. HAMPTON: I should think so. I do not believe he had a perforation at the time of this ex-

amination. We cannot reach a definite conclusion about this lesion, but it certainly looks like carcinoma.

DR. WYMAN RICHARDSON: I saw this man in the Out Patient Department and sent him in with a diagnosis of carcinoma of the stomach. I do not know the answer now, but my diagnosis still holds. I disregarded the long history but wondered if he might not have had previously a diaphragmatic hernia of the stomach.

DR. HAMPTON: I have never seen dilatation of the esophagus to that degree due to carcinoma. That is an enormous esophagus.

DR. MEANS: Do you ever see an esophagus of that size due to diaphragmatic hernia?

DR. HAMPTON: No, I do not believe it would become that large, even with an ulcer at the lower end or a benign stricture.

DR. EDWARD B. BENEDICT: I have never seen an esophagus of that size except in cardiospasm.

CLINICAL DIAGNOSES

Cardiospasm with esophageal dilatation
Bronchiectasis

DR. JONES'S DIAGNOSES

Benign esophageal stricture (chronic)
Cancer (probably of stomach)

ANATOMICAL DIAGNOSES

Dilatation and muscular hypertrophy of esophagus (cardiospasm)
Carcinoma of esophagus with metastases
Abscess in subdiaphragmatic metastasis
Acute pneumonitis with abscess formation
Pulmonary tuberculosis, healed, apical
Arteriosclerosis, generalized, moderate.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The autopsy on this man showed, of course, an enormously dilated esophagus with a frank tumor mass at its lower end, chiefly anterior, but to some extent encircling the esophagus and extending down into the stomach for a short distance. There was also a large tumor mass beneath the diaphragm, lying just anterior to the cardia of the stomach and medial to the spleen, this mass consisted of tumor tissue with a large central abscess cavity and a fistula from this cavity into the esophagus. It seemed to be on the point of rupture into the lesser peritoneal cavity but that had not occurred. The tracheal nodes showed metastases and were very much enlarged. It was obvious that the carina was flattened a good deal. There were metastases to the liver, kidneys and a few other lymph nodes. The

least fifteen years, and possibly twice that length of time, symptoms of esophageal obstruction with gradually increasing obstruction and gradual enlargement in the size of the esophagus. Anything that extends over such a period of time by itself cannot be considered a malignant lesion. Therefore, I should say that the symptoms and story were those of a benign obstructing lesion at the lower end of the esophagus. The x-rays show an enormous barium-filled tube that narrowed down in a funnel-shaped manner to the cardiac orifice. There is no mention in the x-ray report in the record that there is anything but a symmetrical or fusiform narrowing of the lower end of the esophagus. The mass that was first noted by x-ray might have been outside the esophagus or connected to it by a small opening. In other words, it might be a huge esophageal diverticulum under the right clavicle, filled with food and fluid, but it seems more reasonable to assume that the whole picture represents a tremendously enlarged esophagus. It is still possible that there was a diverticulum of the upper third, as a matter of fact the upper third is the weakest portion and does dilate readily if back pressure is put against it. So the x-ray findings fit perfectly well with an obstruction at the lower end of the esophagus and explain part of the clinical picture. I cannot conceive of this obstruction's having been due primarily to cancer at the cardiac end of the esophagus. Fifteen years of continuous symptoms without change in character would seem to indicate a benign process which was gradually increasing.

I suppose it is possible that this process could be a stricture due to previous trauma or to chemical injury following the ingestion of lye. It could be due to congenital narrowing of the lower end of the esophagus or a congenital hypertrophy of the cardiac end of the esophagus. These conditions do occur. We have seen as large an esophagus as this due to cardiospasm of many years' duration. I can recall one that had a story of at least twenty years' duration with a very large esophagus. They do not mention the actual content. I think the largest amount recorded is 1800 or 2000 cc. So far as the size of the dilated esophagus is concerned, any of these benign processes are possible causes, but they will not explain certain other findings. Obviously the man is dehydrated, undernourished and constipated because of lack of sufficient food. He is anemic because of malnutrition. His nonprotein nitrogen is elevated because of dehydration. The only unexplained laboratory finding is the leukocytosis of 31,000 with 88 per cent polymorphonuclears. That goes perfectly well with a pneumonic infection which is

not obvious on these plates but is suggested by the admission chest signs, and we know that he subsequently died with a clinical picture of pneumonia.

We are left with a story of chronic cough and yellow sputum. He may have had bronchiectasis, but the x-ray findings do not suggest any such possibility. This chest plate is an oblique view. It does not suggest a bronchiectatic process to me, nor does it suggest any real pneumonic process. I am not going to consider the story of cough and sputum as related to the main part of the history.

Two months before entry he gives a story of something new — epigastric pain coming ten minutes to one and a half hours after meals, usually relieved by vomiting. Here again we may be dealing with an overdilated esophagus with a certain amount of irritation at the lower end which is relieved by regurgitation. This symptom, however, seems to have a different significance from that of the earlier symptoms.

We have a physical finding which I think is extremely important, that is, an indefinite, hard, tender mass in the epigastrium just below the tip of the xiphoid. That does not go with esophageal disease unless it represents metastases from tumor. I have not seen a sufficient number of cases of cancer of the esophagus to know where they tend to metastasize. I should expect them to metastasize to the mediastinal nodes rather than below the diaphragm. The mass may be associated with the liver, of course, or it may be the stomach, but it has to be one of these organs.

It is entirely possible that we have to make two diagnoses, one of a benign process which is more or less obstructing the esophagus and has done so increasingly over a period of many years, and then a second process which has changed the symptoms recently and at entry is associated with a mass at the tip of the xiphoid. It may represent cancer of the stomach or just outside the stomach and in the liver. I do not believe he has tuberculosis, but the negative 1-40,000 tuberculin test does not rule it in or out. It is of some interest that the Hinton test is negative. It says here "only very small amounts of fluid could get through the cardia." I do not feel at all sure that they knew where the tube was. It is possible it never went below the cardia, and it is also possible that they never entirely emptied the esophagus. I am wondering about the possibility of prolonged irritation at the lower end with possibly an inflammatory process with erosion and ulceration and an abscess below it, which might be the basis of this epigastric mass. The mass is tender, which is not like many malignant processes, but the patient did not come in with

Final Admission (three months later) For about six weeks after discharge she had only very slight difficulty in swallowing, but she developed a dull, constant, aching sensation across the upper part of her abdomen. She also had a poor appetite but no other symptoms. One month before re-entry she again began to have severe dysphagia with regurgitation of almost all solids and liquids. Finally she was practically unable to take anything by mouth and was given rectal feedings. She had lost about 15 lb in weight during the month before re-entry.

Physical examination revealed a cachectic woman, obviously very ill. Her blood pressure was 85 systolic, 65 diastolic. The examination was otherwise essentially negative.

On the day of entry an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. EARLE M. CHAPMAN: The problem here is obviously the diagnosis of a mass which is causing an infiltrating type of lesion in the lower third of the esophagus, particularly on the right side. The record says, "The tumor mass caused marked narrowing of the lumen so that the barium stream was reduced to a trickle and passed very slowly into the stomach." So we know there is a mass obstructing the esophagus. One interesting point is that she first had difficulty in swallowing solid foods, later liquids. It also says that for two weeks she had a remission and was able to swallow solid foods without difficulty. That to me is rather surprising and I am at a loss to explain it. I do not know why in the course of this disease she should suddenly be free of symptoms. One thinks of unusual lesions, such as a polyp which might lie in the esophagus and move or change in position. I do not see how autodigestion could occur while it was in the esophagus, but if it were on a long pedicle and reached into the stomach, that is possible. One thinks of metastases or some process forming an abscess cavity that drained into the esophagus. There is nothing to indicate that it drained into the pleural space or into the lung. I think these are remote possibilities of what might have explained the remission. The x-rays are the most important part of the whole examination. Perhaps Dr. Hampton will show them.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON: These three films were taken at the first examination, we have an examination nearly three months later and another four months after the second. The total time be-

tween the first and last examinations is seven months. The first examination was before irradiation and shows this filling defect at the lower end of the esophagus with dilatation above, which is quite consistent with carcinoma of the esophagus. Then twenty-seven days later, following irradiation, the esophagus is, so far as I can tell, perfectly normal. I do not believe anyone would suspect that the stomach is abnormal.

DR. CHAPMAN: What do you mean by "thickening of the upper part of the stomach in the posterior wall, but no evidence of tumor"?

DR. HAMPTON: It appears straight and rather rigid at that point, but I should not make a diagnosis of intrinsic disease. But four months later there is definite irregularity of the stomach in the same area that was suspected of being abnormal before, and the irregularity in the lower end of the esophagus is of the same general appearance as before x-ray treatment, except that there is less obstruction. In the upright film taken of the abdomen you can see a gas bubble in the fundus of the stomach, which outlines a definite intrinsic filling defect.

DIFFERENTIAL DIAGNOSIS (continued)

DR. CHAPMAN: What is this tumor mass? We know it is there. What is its character? It is obvious to me that carcinoma was diagnosed clinically. It is characteristic of carcinoma from the x-ray finding, and the story is that of carcinoma. Another fact is that she was treated as if she had carcinoma. She received 11,000 r which is the dose given for carcinoma. It did respond to treatment. It would be interesting to know what the esophagus and the mucous membrane showed following such a massive dose of x-ray. It was wise I suppose that a tube was put down during the treatment, because with that amount of treatment over a tumor area she might have perforated and developed mediastinitis if she were allowed to swallow. The fact that she had a tube in place was a precautionary measure. To me, the facts that she had slight thickening of the upper part of the stomach in the posterior wall, and that this disease started higher up in the esophagus and spread down into the stomach, suggest that the lesion was not a carcinoma. The fact that it does not produce great irritation in the lining of the stomach also points to a different type of lesion. It suggests lymphoblastoma of some sort. What type could it be? Hodgkin's disease is extremely rare in the esophagus. I know of one case, however, because I was fooled on it at a similar conference with third-year students. I said on that occasion "Hodgkin's is one type of lymphoblastoma that I

tumor was a squamous cell carcinoma, obviously primary in the esophagus

I should agree entirely with Dr Jones's discussion, though I cannot prove his contention by any anatomical facts. I do not believe a carcinoma of the stomach can give rise to as large an esophagus as this. I think he must have had some form of benign stricture—almost certainly cardiospasm—for years and that the carcinoma was a relatively late, terminal complication.

There was one other finding, at the right base there was pneumonic consolidation with many abscess cavities within the consolidated area, so that the "pneumonia" without much question was really an inhalation pneumonitis from regurgitation and aspiration of material from the esophagus. That is not an uncommon complication in esophageal stricture.

DR. HAMPTON His chest plates ought to have shown bronchopneumonia at both bases, but they are strangely clear.

DR. JONES What is the usual spread of carcinoma of the esophagus below the diaphragm?

DR. MALLORY A fair number will extend across the sphincter and actually invade the stomach for a short distance. The most common spread is to the regional nodes and frequently there is direct extension to the pleura and lungs.

DR. RACKEMANN Did the tumor extend upward far enough to account for the defect in the wall of the esophagus?

DR. MALLORY Yes.

DR. RICHARDSON Is there not a definite inflammation of the esophageal wall in cardiospasm?

DR. MALLORY One can say that the esophageal wall above the tumor is quite hypertrophied in spite of the dilatation. It still is much thicker than a normal esophagus, which would prove anatomically that the obstruction was of long duration, at any rate much longer than the few months of the terminal part of the history. So far as any other specific lesion of cardiospasm is concerned, I am not convinced there is one.

DR. JONES In the ones you have examined do you not find a narrow cardiac orifice with fibrosis?

DR. MALLORY There is always some fibrosis; anyone who has retained food in the esophagus for twenty years should have a little inflammatory reaction to it.

CASE 24142

PRESENTATION OF CASE

First Admission A fifty-five-year-old housewife entered the hospital with the complaint of difficulty in swallowing.

She felt perfectly well until seven months before entry, when she began to have pain in her epigastrium brought on by swallowing solid food. As soon as the food passed a certain point in her esophagus the pain ceased. She was perfectly comfortable when not swallowing. These symptoms continued and became slightly more troublesome until four months before entry, when for a period of two weeks she had a remission and was able to swallow solid foods without difficulty. However, her symptoms returned and for the two months before entry she was able to eat only semi-solid foods and liquids. During the week before entry she even began to have difficulty in swallowing liquids. During her illness she lost at least 20 lb in weight. She had had no nausea, vomiting, hematemesis or melena. Her past history and family history were noncontributory.

Physical examination revealed a well-developed, somewhat emaciated white woman, in no apparent discomfort. Except for emaciation and dental caries, the physical examination was entirely negative. The blood pressure was 106 systolic, 76 diastolic.

The temperature was 98.6°F., the pulse 95. The respirations were 20.

The urine examination was negative. The blood showed a hemoglobin of 75 per cent and a white cell count of 7100 with 66 per cent polymorphonuclears. The blood Hinton test was negative.

An x-ray examination of the esophagus showed a tumor mass infiltrating the right side of the esophagus in its lower third. The tumor caused marked narrowing of the lumen so that the barium stream was reduced to a trickle and passed very slowly into the stomach. The esophagus above the lesion was dilated and showed marked peristalsis. The stomach was normal.

She stayed in the hospital for three months and was given daily x-ray treatments amounting to 11,600 r units. The radiation was given in doses of 200 r through four portals. She was fed by nasal tube for the first two months and was fairly comfortable except for occasional nausea and rare episodes of vomiting. On one occasion she vomited about 100 cc of thin red fluid. After the first two months the tube was removed, and she began taking fluids and soft solids with little difficulty and no pain. Three weeks later an x-ray examination of the esophagus showed no definite lesion. She continued to improve and gain weight, and a week before discharge a repeat x-ray examination again showed an apparently normal esophagus. There was slight thickening of the upper part of the stomach in the posterior wall, but there was no evidence of tumor.

SECTION TWO*

EDITORIAL

THE COMMISSIONER
OF PUBLIC HEALTH

THE functions of the Massachusetts Department of Public Health are many. Its Division of Communicable Diseases, through the district health officers, assists local boards of health in the control of disease, and offers diagnostic aid through the Bacteriological Laboratory at the State House. Its Division of Biological Laboratories manufactures and supplies various biological products for the treatment of disease, and gives diagnostic aid through the Wassermann Laboratory. Its Division of Food and Drugs protects the people of the Commonwealth against the adulteration of food and drugs. Its Division of Tuberculosis is in charge of the state sanatoriums that care for the tuberculous and those with cancer and the sequelae of infantile paralysis, in addition to conducting the tuberculosis-control program and the follow-up work in connection with the Chadwick Clinics. Its Division of Child Hygiene is concerned with all aspects of child health. Its Division of Adult Hygiene conducts investigative and educational work in regard to cancer, diabetes and arthritis. The work of its Division of Genitoinfectious Diseases is largely educational, but this division also subsidizes a number of municipal clinics for the treatment of gonorrhea and syphilis. Its Division of Sanitary Engineering has oversight of water supplies, sewage-disposal systems and the shell-fish industry, certain special engineering projects are carried through each year, and the division conducts an Experiment Station, which has made many important contributions to our knowledge of sanitary engineering. Its Division of Administration, in addition to supervising

the activities of all other divisions and to directing general public-health problems, has charge of the crippled-children's clinics which are financed through grants from the United States Public Health Service and the Children's Bureau.

During 1937 over \$3,200,000 was required to finance all these activities, in addition to federal grants under the Social Security Act of approximately \$400,000. The department employs nearly 1500 individuals, and during the past year furnished 387,000 days of state-sanatorium care to 1900 patients, in addition to that required by 1437 persons admitted to the Pondville Hospital.

The responsibility of directing this huge undertaking rests upon the Commissioner of Public Health, and the people, particularly the physicians, of the Commonwealth have every right to demand that he be experienced and of proved ability, as specified by existing statutes†. Beliefs, political or otherwise, should not influence his selection: the health of the people is far too important to be jeopardized by such considerations, as has been amply demonstrated by the unfortunate series of events in the Department of Mental Diseases during the past two years.

If the excellence of and the notable contributions to public-health administration that have characterized the activities of the Massachusetts Department of Public Health for nearly seventy years are to continue, this department must be under the guidance of one who has had special training and experience in public-health work. The Council of the Massachusetts Medical Society at its stated meeting on February 2 passed a resolution approving of Dr. Henry D. Chadwick's reappointment. *It becomes the duty of all members of the Society to make every possible effort to effect his continuance in office!*

This issue of the New England Journal of Medicine is published in two volumes.

*General Laws: Tercentenary Edition, Chapter 17, Section 2.

have never seen involving the esophagus" But that is what it was

What other type could this be? Perhaps the diffuse, spreading type of lymphosarcoma. We also see diffuse spread of the reticulum-cell and stem-cell types. We know that she responded to x-ray, but the response is no proof of the diagnosis. If this were any form of lymphoblastoma she probably would have responded to a much smaller dose of x-ray. On the other hand the fact that she shows this picture is very suggestive of lymphoblastoma.

As to the final episode when she returned, examination was again negative. I am surprised that physical examination did not show some enlargement of nodes in the neck, groin or retroperitoneal region, or possibly a palpable or enlarged spleen. Her blood pressure had fallen, but I believe we need not think of a cardiovascular accident, such as coronary occlusion. I should think that lymphoblastoma is a good working diagnosis, and it is the best I can offer.

CLINICAL DIAGNOSIS

Lymphoblastoma of the esophagus

DR. CHAPMAN'S DIAGNOSIS

Lymphoblastoma of the esophagus and stomach, probably lymphosarcoma

ANATOMICAL DIAGNOSES

Carcinoma of esophagus with extension to stomach and metastases
Esophagopericardial fistula
Pericarditis, acute fibrinopurulent
Empyema, right.
Pulmonary infarct.
Operative wound gastrostomy
Cholecystitis, chronic
Cholelithiasis

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY With any tumor in this area I think it is impossible to distinguish clinically whether it starts in the stomach or esophagus. X-ray examination may be misleading, and sometimes it is even impossible at autopsy. Histologic examination usually settles the issue, but once in a while it is difficult even when all the facts are in. I think I should explain why such a massive dose of x-ray treatment was given to this patient. A biopsy was done and on a section which was sent to us from another laboratory we found obviously malignant tumor cells, predominantly spindle-shaped, and we made a diagnosis of leiomyosarcoma. That is not a radiosensitive tumor, and our report undoubtedly influenced the x-ray department to use the maximum dose. They were then quite astonished to see the disease melt away. If it really had been a leiomyosarcoma even after such a dose it probably would not have been affected. The tumor, as you have seen, recurred fairly promptly, and at the time of autopsy we found a large tumor involving both the lower end of the esophagus and the cardia of the stomach. There was ulcerated tumor extending 4 cm above the cardia, and a fungating mass which extended down into the stomach for 6 or 7 cm. The tumor had grown through the posterior wall of the stomach and was invading the pancreas. There was a perforation through the esophageal portion of the tumor into the pericardium, with a terminal pericarditis. There was also an empyema. We could not discover any fistulous tract connecting the esophagus and the empyema. On microscopic examination it was quite evident that it was an epidermoid carcinoma which must have been primary in the esophagus. It was of a very high grade of malignancy. These very undifferentiated epidermoids are fairly sensitive to radiation, and the temporary response is therefore not surprising.

U.S.P. UNITS FOR LIVER EXTRACT

With the preparation of the first extracts of liver for use in pernicious anemia it became apparent that variable losses of potent material occurred, depending on the method of manufacture. Nevertheless, until quite recently, in describing such products reference has usually been made to the amount of liver used in their preparation rather than to the potency of the final product.

The first step toward a better definition was taken a few years ago by the Council on Pharmacy and Chemistry of the American Medical Association, which established for acceptable products certain minimal requirements in terms of hematopoietic power when given in reasonable dosage. With the eleventh revision of the *Pharmacopoeia of the United States*, the determination of the potency of preparations of liver or stomach was referred to the Anti-anemia Preparations Advisory Board. To this board, various manufacturers have

submitted data as to the clinical effectiveness of certain preparations of liver administered in a specified manner, and from these data the board has assigned a unitage to each product. Elsewhere in this issue will be found a definition of the meaning of these units, whether for "oral" or for "injectable" products, together with a list of values in terms of units for each preparation at present accepted.

It is to be emphasized that, although a unit of material prepared by different manufacturers may be expected to produce similar hematopoietic effects in pernicious anemia, it is not known that units of all preparations will have similar effects on gastrointestinal and neural manifestations. There is some evidence to suggest that even the hematopoietic effect of preparations of liver depends on multiple factors rather than a single chemical entity, and it is possible that with different manufacturing processes variable amounts of substances with a particular effectiveness, respectively, on the gastrointestinal and the neural manifestations of pernicious anemia have been retained. Such differences are perhaps especially likely to appear in the treatment of atypical patients or in related conditions such as sprue or the pernicious anemia of pregnancy.

The number of products accepted by the board means that no physician need use products not so listed. Although certain eminently satisfactory products do not appear in the present list, the board expects to assign unitage to new products which may be submitted, it will also re-evaluate products according to new clinical data. By comparison of the unitage, the relative concentration and the bulk of these products, the physician should be able to select the preparation most suitable for his purpose. With a knowledge of the price of the various preparations he should be able to estimate the comparative cost per unit of potency of different preparations. At any rate, an important step in the right direction has been taken in that the medical profession now has available a better knowledge of the potency residing in the final product, irrespective of how much effective material may have been lost or discarded in the manufacturing process.

noted on admission was treated with ferrous sulfate, 12 gr. daily

On February 12 x-ray examination showed the occipitofrontal diameter of the baby to be 11.3 cm., predicting an infant of minimum weight of 5 lb. On February 14 under gas-oxygen anesthesia and with all aseptic precautions, a vaginal examination was done which revealed the os to be easily patulous to one finger, the placental margin was felt 4 cm. within the internal os on the anterior surface of the lower uterine segment. An immediate abdominal cesarean section of the classical type was done with delivery of a 6 lb., 4 oz., female child in good condition. Both patient and baby made an uncomplicated recovery and left the hospital on March 3 in good condition, the baby weighing 6 lb., 6 oz.

Comment Vaginal bleeding, no matter how slight in amount, in the early part of the last trimester of pregnancy must always be looked upon as potentially serious, as was done in this case. At this time, of course, the baby's viability is extremely doubtful no matter what method of delivery is contemplated. Hospitalization is imperative. Slight bleeding may be the precursor of extreme bleeding. A vaginal examination when the bleeding ceases to determine the exact cause of the bleeding is unwise because of the possibility of starting up a hemorrhage which will make delivery imperative to save the mother's life, and there is then practically no chance of a live baby. The use of x-ray measurements to determine the degree of prematurity is well worth while. In this case it gave results which definitely influenced the time of operation. It must be borne in mind, however, that it is not an infallible procedure as its results are not uniformly accurate. It may well have been, in spite of the successful outcome of this case, that another week or ten days before a final examination was undertaken would have assured a baby whose chance of survival would have been more enhanced by the extra period of intrauterine life, but it may be argued that if operation had been delayed ten days, a serious hemorrhage might have occurred. When any such case is examined, everything must be ready. There is no mention in this case of having a compatible donor at hand. This constitutes added safety for the mother and is a routine procedure which often saves life.

In the treatment of marginal placenta previa a bag is sometimes used, and sometimes the membranes are ruptured. Rupture of the membranes is rarely successful unless the patient is in labor. The use of a bag through an undilated cervix in a patient who is not in labor and is not bleeding is not so safe for the baby as an abdominal section. It carries with it the risk to the mother of added

bleeding which the abdominal operation does not entail

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 11

BARNSTABLE

The session scheduled for Easter Sunday, April 17, has been postponed to Sunday, May 1. John I. B. Vail, *Chairman*

BERKSHIRE

Thursday, April 14, at 4:30 p. m., at the House of Mercy Hospital, Pittsfield. Subject: Early Syphilis. Instructor: Francis M. Thurmon. Melvin H. Walker, Jr., *Chairman*

BRISTOL SOUTH (Fall River Section)

Monday, April 11, at 4:30 p. m., at the Union Hospital, Fall River. Subject: Cesarean Section, Analgesia. Instructor: M. Fletcher Eades. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*

ESSEX NORTH

Friday, April 15, at 4:30 p. m., at the Lawrence General Hospital, Lawrence. Subject: Cesarean Section, Analgesia. Instructor: M. Fletcher Eades. John Parr, *Chairman*

FRANKLIN

Wednesday, April 13, at 8:00 p. m., at the Franklin County Hospital, Greenfield. Subject: Pneumococcus Pneumonia and Serum Therapy. Instructor: Frederick T. Lord. Halbert G. Stetson, *Chairman*

HAMPDEN

Thursday, April 14, at 4:00 p. m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p. m., in the Out-patient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject: Some Complications of Labor Analgesics in Labor. Instructor: Raymond S. Titus. George D. Henderson and George L. Schadt, *Chairmen*

HAMPSHIRE

Wednesday, April 13, at 4:15 p. m., in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject: Recent Advances in the Diagnosis and Treatment of Heart Disease. Instructor: Burton E. Hamilton. Warren P. Cordes, *Chairman*

MIDDLESEX SOUTH

Wednesday, April 13, at 4:00 p. m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject: The Use of Vitamins in Pediatric Practice. Instructor: Louis K. Diamond. Edmund H. Robbins, *Chairman*

NORFOLK

Friday, April 15, at 8:30 p. m., at the Norwood Hospital, Norwood. Subject: Acute Anterior Poliomyelitis—Its Diagnosis and Treatment. Instructor: Charles F. McKhann, Jr. Hugo B. C. Riemer, *Chairman*

JOURNAL OF NEUROPHYSIOLOGY

A NEW medical journal, reflecting the rapid advance in our knowledge of the physiology of the nervous system, named the *Journal of Neurophysiology*, was issued for the first time in January, 1938. This journal has distinct aims, somewhat different from those of almost any other publication. In the first place, it plans to provide a channel for the prompt publication of original work, embracing all aspects of the subject amenable to experimental analysis. The journal will be published six times a year and an editorial board of three has been organized to reach prompt decisions on all contributions submitted. Papers to be published will be selected four weeks prior to their appearance, and it is hoped by this means that papers will actually appear in their printed form within two months or less after their receipt by the editors. Thus, along with a careful editorial policy in regard to literary form, should make this journal unique among medical publications. The members of the editorial board—J. G. Dusser de Barenne, J. F. Fulton and R. W. Gerard—are sufficiently well known in the field of neurology and physiology to justify the expectation that this journal will not only have a wide field of usefulness, but that the editors will uphold the strict rules which they have laid down. The *New England Journal of Medicine* extends its best wishes to this new journal of so much promise.

CASE HISTORY No. 66 MARGINAL PLACENTA PREVIA

Mrs. M. B., aged thirty years, was seen at home on January 23, 1936, in the thirty-first week of her fourth pregnancy. Shortly before the visit she had passed some blood by vagina, "just like the be-

ginning of a period." There was no pain or cramps.

Her family history was negative. Her past history included measles, mumps, chickenpox and pertussis in childhood and influenza at thirteen. Her tonsils had been removed at the age of four, and she had injured her right kidney in a coasting accident at sixteen without, however, any serious sequelae. Her catamenia, which began at twelve or thirteen, were of the twenty-six to twenty-eight day type and lasted five or six days without pain. Her last period was June 25, making the expected date of labor April 1 to April 4. Mrs. B. had given birth to one child, who was now ten years of age. Her second and third pregnancies had been interrupted by induced abortions in 1928. The present pregnancy had been normal to date, and she had had no previous medical supervision.

Physical examination showed a well-developed and nourished woman, lying comfortably in bed and in excellent general condition. Her temperature was 98°F, pulse 80, respirations 20, and her blood pressure was 122 systolic, 74 diastolic. Her color was good, her eyes, nose, throat and neck were negative, and her teeth were well cared for. The breasts showed the usual signs of pregnancy. The heart showed no enlargement, there were no murmurs. The lungs were normal, there were no rales. The uterus corresponded in size to a seven months' pregnancy and was neither tender, spastic nor in labor. The fetus was presenting in LOA position, with the vertex unengaged, the fetal heart rate was 156. A vulvar pad worn by the patient showed a small amount of dark blood, and the total estimated quantity of blood lost did not exceed half an ounce.

The patient was at once transported by ambulance to the hospital, where further studies showed a urine negative for albumin and sugar, a hemoglobin of 70 per cent (Sahli), a red-blood-cell count 3,820,000 and a normal blood smear. X-rays taken for measurement of the fetal head by stereoradiography showed the occipitofrontal diameter to be 10.3 cm.

A policy of watchful waiting was pursued because, first, the bleeding had been slight in amount and insufficient to jeopardize in itself the life of the patient or her baby, secondly, the latter was a dubious risk for immediate delivery by any method, and thirdly, the patient agreed to remain in the hospital until viability of the infant could be assured provided no further bleeding occurred. A very small amount of brown staining occurred on January 24 and January 30, while her general condition, blood pressure and urine remained normal. The slight degree of hypochromic anemia

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

this request is a larger issue than the mere righting of a single wrong. It is the feeling in our minds that the *Journal* should maintain the same unprejudiced attitude toward the social and economic problems of medicine and public health that it holds toward clinical problems, providing an open forum with room for minority opinion and welcoming any new ideas which are honestly and intelligently presented. Furthermore, in our opinion the *Journal* should seek to stimulate similar free and open discussion among local medical societies and in local medical journals. We believe that if such an attitude is encouraged by the Board of Trustees, these Principles and Proposals will receive unprejudiced consideration before and at the 1938 meeting of the American Medical Association in California.

We are sure that your board will agree that if any argument or controversy arises it should be conducted in a dignified manner, on the usual plane of scientific disagreement by presentation of observation and inference, without recourse to irrelevant personalities and unsupported by the weapons of ridicule and innuendo which, we protest, have characterized certain editorials of our *Journal*.

We ask

1. Publication in the *Journal* of our communication of December 8
2. An agreement to open the pages of the *Journal* to reasonable and honest discussion of social and economic problems concerning the provision of medical care.
3. That all discussion of these problems be kept on a plane consonant with the dignity of the profession of medicine.
4. That you give us a prompt answer so that we may determine our future course.

After discussion that lasted until 3 p. m. the Board of Trustees passed the following votes

1. That the statement submitted by the committee under date of December 8 for publication in the *Journal* be suitably edited, as are all communications offered for publication in that periodical, and that it be then submitted to the Committee of Physicians for approval.
2. That there be more discussion in the *Journal* of social and economic problems concerning the provision of medical care with the presentation of various aspects of the subject.

By agreement no notice of the purposes or results of the meeting were given to the press, except the statement that an amicable solution of the differences between the two parties might be expected.

On February 26 the committee convened in New York City to consider the results of the Chicago meeting. Before this there had been received from Dr. Morris Fishbein an edited version of the committee's statement together with an editorial comment. These were taken the same evening, with the criticisms of the committee, by Drs. Weiss and Peters to Dr. Fishbein, who was staying in New York. With one exception the suggestions of the committee were accepted. Both the editorial comment and the statement of attitude and intent were thereupon forwarded to the *Journal* for publication March 12 with the understanding that no additional remarks would be printed at this time.

This objective having been attained it has become nec-

essary to consider the further course of action of the committee and the signators.

The animosities first aroused by the public appearance of the Principles and Proposals are giving way to more mature consideration. There can be no doubt that the Principles and Proposals have aroused healthy discussion of the subject with which they are concerned.

Although the Principles and Proposals have no absolute value and should not be considered unalterable, they constitute the instrument which has united and stimulated a large group of physicians. The very general form of their statements allows latitude of interpretation without degradation of spirit and makes them a large common denominator of liberal medical opinion. For the present, then, they may well be retained entire as a tentative platform.

It is clearly recognized that the self-appointed committee should eventually give way to some more representative body appointed by democratic methods. Already, in the interests of more equitable representation, the committee has been enlarged. It now consists of the following men:

Dr. Russell L. Cecil (chairman), Dr. Hugh Cabot (vice-chairman), Dr. Milton C. Winternitz (vice-chairman), Dr. John P. Peters (secretary), Dr. George Blumer, Dr. Allan M. Butler, Dr. Louis Casamajor, Dr. Thomas B. Cooley, Dr. J. Rosslyn Earp, Dr. Channing Frothingham, Dr. L. Emmett Holt, Dr. William S. Ladd, Dr. William S. McCann, Dr. George R. Minot, Dr. Hugh Morgan, Dr. Robert B. Osgood, Dr. Richard M. Smith, Dr. John H. Stokes, Dr. Borden S. Veeder, Dr. James J. Waring, Dr. Soma Weiss.

The committee is receptive to suggestions for reorganization along representative democratic lines. Suggestions from individual signators or groups of signators for a future program will also be welcomed.

The committee has felt from the outset that the Principles and Proposals were composed by and for physicians. Although they have received the approval of great numbers of laymen and of lay organizations devoted to medical, social and economic projects, the committee has merely acknowledged this approbation. It has sedulously refused all offers of support from lay sources. It has even refrained from participation in public programs fostered or sponsored by lay groups. All its activities since November 7 have been financed by voluntary contributions from members of the committee and a small number of signators.

INTERNATIONAL BROADCAST ON RHEUMATIC HEART DISEASE

Leading British and American physicians, 6000 miles apart, will confer via the radio on the greatest menace to child health, rheumatic heart disease. This conference, the first international broadcast on any health problem, will be heard over the Red Network of the National Broadcasting Company on Monday evening, May 2, at seven-thirty o'clock Eastern D.S.T. Arranged by the American Heart Association, the conference broadcast will observe National Child Health Day.

Lord Thomas Jeeves Horder, physician-in-ordinary to the King of England, will open the conference speaking from London. Dr. Homer F. Swift, of the Rockefeller Institute, New York City, and Dr. T. Duckett Jones, of the House of the Good Samaritan, Boston, will then speak from Atlantic City where they will be attending the

DEATH

TURNER—RALPH GORDON TURNER, M.D., of 1565 Main Street, Walpole, died at his home, March 26. He was in his thirty-second year.

Born in Marlboro, he was graduated from Dartmouth College in 1928 and received his degree from Rush Medical College, University of Chicago, in 1933.

Dr. Turner was a member of the American Medical Association, a fellow of the Massachusetts Medical Society and held memberships in the Phi Sigma Kappa and Alpha Kappa Kappa fraternities.

His widow, two brothers and his parents survive him.

MISCELLANY

COMMITTEE OF PHYSICIANS

Following the numerous discussions of the Principles and Proposals by medical societies throughout New England many physicians will doubtless be interested in an abbreviated form of the statement sent by the Committee of Physicians to the endorers on March 2.

* * *

As a result of the editorial of October 16 in the *Journal of the American Medical Association* the Principles and Proposals with the list of signators were treated on November 7 to unfortunate publicity in the lay press, despite the best efforts of the committee. Especially unhappy was the general impression that the proponents of the Principles and Proposals were revolting against the American Medical Association. Although this impression arose directly from the *Journal of the American Medical Association* editorial, which had been released to the press before publication, the onus for the publicity fell largely on the committee. The immediate consequence was the withdrawal of a certain number of signatures and a sudden retardation in the growth of the list of endorers. In addition to those who withdrew unconditionally a large number asked that their names be not used until they received further information concerning the past course and future intentions of the committee. (It is appropriate to state that very few of those who withdrew claimed that they were unaware of the nature or purpose of the Principles and Proposals.)

The *Journal of the American Medical Association* editorial had so misinterpreted the actions and intentions of the committee and the signators that it became at once apparent that the true issues raised by the Principles and Proposals were being obscured by discussion of irrelevancies. At this time the most important immediate objectives in the opinion of the committee were to obtain a hearing before the Board of Trustees of the American Medical Association and to secure the right to state its position in the *Journal of the American Medical Association* thus correcting the false impressions created by the editorial of October 16. Although a second editorial published on November 27 purported to have the sanction of the trustees, the committee had received no formal intimation that this body had taken any action with respect to the Principles and Proposals or their sponsors. They therefore on November 20 requested a hearing before this body and on December 8 asked the trustees to authorize publication in the *Journal of the American Medical Association* of a statement explaining the attitude and intent of the committee. At its meeting in December, the Board of Trustees of the American Medical Association invited the committee to send representatives to the meeting of the trustees in Chicago, February 17. Consideration of the publication of the committee's state-

ment was postponed until the same date and all efforts of the committee to secure earlier action were fruitless.

On February 17 at 11 a. m. a delegation from the committee, consisting of Dr. Hugh Cabot, chairman, Drs. Cooley, Holt, Morgan, Osgood, Peters and Veeder, appeared before the Board of Trustees and presented the following statement:

We appear before the Board of Trustees as delegates of a self-appointed committee, who represent the feelings of a considerable group of members of the American Medical Association. Interest in this common cause has in no sense altered the allegiance of this group to the American Medical Association. We therefore welcome the opportunity to appear before its governing body. The subject which we wish to discuss with you, first, is the purpose of the Principles and Proposals, which, we believe, have been both misunderstood and misinterpreted. Although these arose under the stimulus of the American Foundation's report, *American Medicine*, they were not derived from this report, nor did they emanate from the American Foundation or from any source other than the minds of certain members of this committee. After deliberation a consensus was achieved. It represents the greatest common denominator of these personal opinions concerning the directions which the policies of the organized medical profession of the United States should take in order to advance the quality of medical care. Its purpose was also to forestall untimely and unwelcome lay and governmental interference by demonstrating the openmindedness and declaring the good will of the medical profession and its desire to assert its prerogative as an expert body to lead all movements to improve medical care. It was hoped that the draft might create healthy discussion, and progressive action throughout the country if it were presented to the American Medical Association and its component societies. This feeling was strengthened by the reports of the reference committee to the House of Delegates at Atlantic City in 1937 concerning a slightly modified draft presented by the New York State delegation.

Unfortunately, an editorial appeared in the *Journal of the American Medical Association* of October 16, condemning the Principles and Proposals and intimating that their authors and endorers were acting in contravention of the policies of the American Medical Association and of the best interests of American medicine. This editorial and others which followed have, we believe, put an unfortunate color upon the publicity which the Principles and Proposals have received, they have beclouded the true issues with irrelevancies and have militated against the unprejudiced consideration of a subject which is as dear to the American Medical Association as to ourselves, namely the advancement of measures for the improvement of medical care.

We therefore submitted for publication in the *Journal* of our association a statement of our attitude and intent, to correct what we consider to be erroneous impressions that have arisen from these editorials. This statement was presented to this board on December 8, 1937, two months ago. We believe that the democratic organization of the American Medical Association and the editorial integrity of the *Journal* justify us in asking this board to expedite its publication, which has already been long delayed. Belund

incorporated as a nonprofit organization. The Aetna Life Insurance Company is offering a plan for hospitalization insurance, very similar to that established by the Plan for Hospital Care. Under both, insurance is limited to groups employed in stores, factories, offices and in industries. Groups of 10 persons employed by the same firm, and their families, are insurable under the Plan for Hospital Care. The Aetna plan has been launched among concerns that now carry group life insurance policies with the company, and requires signatures of 75 per cent of the employees covered by the group life policy. Only actual employees are covered, but it is said that the service will soon be extended to include the members of their families.

The Aetna plan provides benefits of \$400 a day at monthly cost to the insured of 77 cents. Coverage is for seventy days during any one disability, except that if the disability is due to pregnancy the benefits are for a maximum of fourteen days. In addition to the benefit, the employee, under the Aetna plan, is entitled to reimbursement for any fees actually charged for anesthetics or their administration, for the use of operating room and for laboratory fees, excluding x ray fees, up to a maximum, during any one disability, of five times the daily benefit. Employees under seventy years of age are eligible and may be insured until that age is reached.

The Plan for Hospital Care limits the benefits to twenty one days in any one year, and covers a bed in semi-private accommodations, meals, general nursing care, operating room service, all medications, all surgical dressings, routine laboratory services, oxygen and serums, basal metabolism tests, ambulance service within three miles radius of the member hospital, maternity delivery room service (one year after subscriber joins plan) and ordinary nursery care of newborn baby. If any subscriber takes a private room, he is allowed \$4.50 a day credit on its cost. If he is taken to a non-member hospital, he receives a cash credit of \$600 a day against his bill. For 50 cents a month additional, the wife or husband of a subscriber is covered, and for 25 cents a month all children that have not reached their nineteenth birthday are included. Dependents of subscribers, however, are required to pay the hospitals \$100 a day to get the same benefits that are payable to subscribers. The Plan for Hospital Care does not accept persons who have reached their sixtieth birthday, but once one is enrolled one may continue indefinitely. The Plan for Hospital Care does not include the cost of anesthesia, physiotherapy, x-ray and electrocardiography.

Neither plan makes any provision for the payment of physicians and surgeons fees. Neither plan permits an individual to join independently of the groups in which he is employed, and in both plans the premiums are paid by the employers, who are authorized by the insured to deduct them from their pay each month.

DOCTORS ALONE ELIGIBLE FOR HEALTH POSTS

Every town, city and borough in Connecticut must have a health officer who is a licensed practitioner of medicine according to an opinion handed down by the Deputy Attorney. The law does not require, however, that the health officer be a resident of the town or city where he officiates.

RESULTS OF PREMARITAL BLOOD TEST

From data available for 1937 there were considerably more cases of syphilis uncovered as a result of the premarital blood test than in 1936. Syphilis occurred about

equally in men and women. From the standpoint of prevention of congenital syphilis the tests on women are most important.

INSPECTION OF INDOOR WATER POLLUTION

The first local survey of water supplies of buildings was started in Hartford in 1937. Since then surveys have been started in New Haven, Bridgeport, New Britain and Waterbury. In the Hartford inspection from March through December, ninety six buildings were included. Inadequately protected drinking water tanks were found, and several direct connections to sewers from water lines through refrigeration and air-conditioning equipment were discovered. In all cases building owners and managers have been willing and even anxious to make any desired improvements after the hazards have been explained.

HEALTH-OFFICER APPOINTMENTS

Ernest R. Pendleton, M.D., has been appointed health officer of Granby replacing Mr. Wesley N. Clark, resigned.

Eugene N. Cozzolino, M.D., has been appointed health officer of West Haven to fill the vacancy caused by the death of Charles E. Kaufman, M.D.

H. R. Hansell, M.D., has been appointed health officer of Sharon during the absence of Jerome S. Chaffee, M.D.

John E. Stoddard, M.D., has been appointed health officer of Meriden to succeed Michael J. Sullivan, M.D.

Winfield E. Wight, M.D., has been appointed health officer of Thomaston to replace J. H. Kane, M.D., resigned.

DEATHS

O'CONNELL—THOMAS S. O'CONNELL, M.D., seventy-one, of 59 Burnside Avenue, East Hartford, for nearly half a century a practicing physician in that town and its representative in the last session of the General Assembly, died at St. Francis Hospital, February 25, after a long illness.

For forty years a member of the East Hartford School Board, Dr. O'Connell had long been an outstanding member of the High School Committee besides serving as school physician. He was also an East Hartford fire-district commissioner, and served several terms as Democratic town chairman. He was examining physician for several insurance companies and for many lodges.

Born in Colchester, December 15, 1866, he was educated in the public schools and at Bacon Academy. He began to teach school when he was nineteen years old, and four years later entered the Baltimore College of Physicians and Surgeons. He was graduated near the top of his class in 1892. His practice in East Hartford opened in August, 1892, was continued until his final illness.

He leaves a son, Judge Richard D. O'Connell, of the East Hartford Town Court, a daughter, Mrs. Frederick Welsh, of Irvington, New Jersey, two brothers, Judge Michael D. O'Connell, of Stafford Springs, and John O'Connell, of Lynn, Massachusetts, two sisters, Miss Margaret O'Connell, who lived with him in East Hartford and Miss Anne O'Connell, of Colchester, and two grand children.

PRATT—EDWARD LOOMIS PRATT, M.D., seventy-nine, a leading physician in Winsted for fifty-three years and one of the founders of the Litchfield County Hospital, died March 4.

Dr. Pratt was born November 2, 1858, in Ravenna, Ohio, the son of Dr. Henry Pratt and Anna (Barnes)

annual meeting of the American Society for Clinical Investigation Dr William J Kerr, president of the American Heart Association, will take up the discussion from San Francisco

Rheumatic heart disease is now recognized as the deadliest and most crippling affliction of children of school age. Its annual mortality rate is seven times that of dread infantile paralysis during an epidemic, while every year it invisibly cripples thousands more. Close to a million persons in the United States have hearts damaged by rheumatic fever.

Lord Horder's discussion will dwell upon public-health aspects of the disease, particularly in England. The radio audience will then be carried to Atlantic City to hear Dr Swift describe the medical investigations being carried on to isolate the cause of the disease. Dr Jones will follow with a discussion of the treatment of children with crippled hearts, emphasizing the need for long-continued sanatorial care. Dr Kerr, from the West Coast, will tell of the work of the American Heart Association in this field.

This international conference broadcast was conceived by a committee of Irvington House, sanatorium for the care of children with heart disease at Irvington-on-Hudson, New York, in an effort to stimulate greater public interest and action in this major child health problem. It will acquaint doctors, and particularly parents and teachers, with the challenge of rheumatic heart disease, more dangerous because of the lack of knowledge of its nature and the difficulty in recognizing its early symptoms. Although no effective cure has yet been found, it is hoped that this broadcast will be a first step in the earlier recognition of the disease which, if unchecked, finally incapacitates the heart. A widespread realization of its prevalence should encourage increased support of scientific studies along these lines.

The present difficulty in arousing the attention of the public to rheumatic heart disease lies partly in its undramatic nature. Compared with the explosiveness and rapid pace of most childhood diseases, it plays the triumphant but unspectacular role of the tortoise in the fable of the tortoise and the hare. It is not easy, without specific education, to recognize the first slow manifestations of rheumatic heart disease as the onset of a systemic disease which may forever cripple the heart of a child.

CONNECTICUT NEWS

NEW HEAD OF NEW HAVEN HOSPITAL

The Board of Directors of the New Haven Hospital has announced the appointment of James A. Hamilton, of Cleveland, Ohio, as superintendent of the hospital to succeed Dr Albert W. Buck, who assumed the superintendency of the Charlotte Hungerford Hospital in Torrington on January 1.

Mr Hamilton was graduated from Dartmouth College in 1922 and obtained his master's degree in 1923 from the Amos Tuck School of Business Administration. He was assistant professor of industrial management at Dartmouth from 1923 to 1936 and for ten years superintendent of the Mary Hitchcock Memorial Hospital at Hanover, New Hampshire. He is at the present time superintendent of the Cleveland City Hospital and lecturer at Western Reserve University. Mr Hamilton plans to take up his work on September 1 after a summer vacation in California.

DR. MACCARTY OF MAYO FOUNDATION SPEAKS

Dr William Carpenter MacCarty, professor of pathology at the Mayo Foundation at Rochester, Minnesota,

and one of the nation's foremost authorities on cancer, was one of the speakers at the first of the 1938 meetings of the Association of Connecticut Tumor Clinics held at St. Francis Hospital on February 24. About 100 persons, among them representatives from hospitals throughout the State, attended the meeting over which Dr L. P. Hastings, chairman of the tumor group, presided. Papers and clinical cases were presented by the members of St. Francis staff, including Drs Edward J. Whalen, Richard C. Buckley and Andrew F. Resnisky. Following the medical education meeting, those attending were entertained at a dinner as guests of the hospital.

DR. CARL WAGNER OPENS SANATORIUM

Dr Carl P. Wagner, former senior psychiatrist at the Hartford Neuro-Psychiatric Institute of the Hartford Retreat, has opened a new private sanatorium for the treatment of a limited number of convalescent, nervous and mild mental patients on the former Alfred Gildersleeve estate on Marlborough Street, Portland.

The institution, called Elmcrest Manor, is on the crest of a hill overlooking the Connecticut Valley. It is housed in a large white mansion, built in 1815, set almost in the center of eight acres of grounds and surrounded by tall, old elm trees and formal gardens. There are separate three-bed wards for men and women patients, semi-private rooms and private rooms.

Dr Wagner, a native of Culbertson, Nebraska, is a graduate of the University of Nebraska and of its College of Medicine. He has served as an instructor in psychiatry at the University of Colorado School of Medicine and from 1930 to 1932 was instructor in psychiatry at Yale University School of Medicine. For the last six years he has been senior psychiatrist at the Neuro-Psychiatric Institute.

DR. OSBORN, STATE COMMISSIONER OF HEALTH, INJURED

Dr Stanley H. Osborn was injured on March 12 when his car left the road and turned over near the town of Ashford in Eastford. Dr Osborn was removed to the Day Kimball Hospital in Putnam.

DR. HUNT PRESENTS HIS PLAN

Dr Ernest L. Hunt, of Worcester, Massachusetts, presented his plan of voluntary co-operation of local medical and social service organizations before a meeting in Hartford on March 9 sponsored by the Medical Information Bureau. This plan has been approved by the Council of the Massachusetts Medical Society but as yet has not been put into operation.

HOSPITAL INSURANCE

Hospital insurance in Connecticut is already operating in New Haven, Waterbury, Milford and Norwalk. The plan sponsored by the State Hospital Association and now operating in the above mentioned towns and cities except Norwalk probably will soon be extended throughout the State.

Robert Parnall, manager of the plan, says that the organization has just closed the twelfth enrollment month, and that a little more than 13,000 persons have joined the plan during its first year in New Haven. The figure is about 10 per cent of the population of the city. About a month ago the hospitals in Waterbury were accepted as 'member hospitals,' and residents of Waterbury were elected to the Board of Directors of the plan, which is

case the response of the patient to the liver extract in question was studied particularly with respect to the reticulocyte and red-blood-cell production resulting from the daily administration of a uniform amount of each preparation. The nature of the preparations submitted has been either dry liver extract (*extractum hepatis*), liquid extract of liver (*liquor hepatis*) or parenteral solution of liver (*liquor hepatis purificatus*), as defined in the *U.S. Pharmacopoeia* Eleventh Revision.

Because of the variation in the efficiency of different processes of manufacture, the therapeutic activity of the final product does not necessarily correspond to the amount of liver from which it was derived. It is therefore necessary to define the therapeutic activity of the final product in other terms. Accordingly, the board has assigned to each acceptable preparation a value in terms of units. The amount of material constituting a "unit" is considered to be that amount of material which, when given daily to patients with pernicious anemia, has produced a satisfactory hematopoietic response. Since in the average case material derived from about thirty times as much liver must be given by mouth to produce the same response as when given by injection, it has been necessary to define the "unit" either as an oral unit or as an injectable unit, according to the intended method of administration of each preparation.

Accordingly, it is understood that on labels, bottles or cartons, or in advertising circulars, the manufacturer whose products have been assigned unitage by the board shall no longer state the number of grams of liver employed in making the preparation, but merely either the number of cubic centimeters or grams of material constituting a unit. Depending on the method to be used in the administration of the preparation, the unit will be defined as either an oral unit or an injectable unit. Definition of the number of units in a preparation for oral administration in terms of "injectable" units or vice versa is not permitted. It is further understood that if any dosage is suggested by the manufacturer, the dosage recommended should not be less than one unit a day, whether given daily or at longer intervals. The wording on the label or in the package literature concerning the unitage will give the following information: "The daily (oral, intramuscular) administration of—(no gm., cc.) (capsules, teaspoons, and so forth) of material prepared by the method employed in producing the contents of this (bottle, vial, package, and so forth) has been demonstrated to produce a satisfactory hematopoietic response in pernicious anemia, and constitutes a unit according to the *U.S. Pharmacopoeia* Anti anemia Preparations Advisory Board."

In general it is recommended that, without good evidence that no harm will result, the amount of material administered should probably not be less than one unit a day, whether given daily or in multiple amounts at longer intervals. In many instances it is probable that the clinical indications will render it advisable to give the patient much more than a dosage averaging a unit a day. It must be recognized that the amount of material constituting a unit is determined largely on the basis of the hematopoietic response and does not imply that such an amount is necessarily effective in the control of gastrointestinal or neural manifestations. Furthermore, there is some evidence that the effectiveness of different types of preparations, although similar when defined in terms of units with respect to blood formation, may differ in their effectiveness upon the gastrointestinal or neural manifestations. A full discussion of the indications for the administration of liver preparations is obviously outside the scope of this announcement through the co-operation of

the American Medical Association and the Committee of Revision of the *U.S. Pharmacopoeia*; a special article on this subject has been published, "The Use of Drugs in the Treatment of Anemia" (*J. A. M. A.* 107, 1633-1636, 1936).

The board will, as occasion arises, re-evaluate products based on new clinical data or assign unitage to new products submitted by manufacturers and accepted by the board.

U.S. Pharmacopoeia ANTI ANEMIA
PREPARATIONS ADVISORY BOARD,
C. W. EDMUNDS, M.D., *Chairman*
WILLIAM B. CASTLE, M.D.,
RAPHAEL ISAACS, M.D.,
GEORGE R. MINOT, M.D.,
W. W. PALMER, M.D.

* * *

The Anti-anemia Preparations Advisory Board has designated below the unitage of the acceptable liver products of the following manufacturers and distributors

Abbott Laboratories, North Chicago, Illinois

1 *Liquor Hepatis Purificatus* Parenteral Solution of Liver

In the following dilutions

(a) 0.1 cc. equals 1 unit (injectable)

(b) 0.2 cc. equals 1 unit (injectable)

2 *Extractum Hepatis* Dry Liver Extract

Powder in capsules. 50 capsules (25 gm.) equal 1 unit (oral)

Armour and Company, Chicago, Illinois

1 *Liquor Hepatis* Liquid Extract of Liver
45 cc. equal 1 unit (oral)

2 *Extractum Hepatis* Dry Liver Extract
9 capsules (4.5 gm.) equal 1 unit (oral)

Basic Endocrines, Inc., San Francisco, California

Extractum Hepatis Dry Liver Extract
50 capsules (25 gm.) equal 1 unit (oral)

George A. Breon and Company Inc., Kansas City, Missouri

Liquor Hepatis Purificatus Parenteral Solution of Liver

In the following dilutions

(a) 0.1 cc. equals 1 unit (injectable)

(b) 0.2 cc. equals 1 unit (injectable)

(c) 0.3 cc. equals 1 unit (injectable)

(d) 0.4 cc. equals 1 unit (injectable)

Buffalo Pharmacal Co., Buffalo, New York

1 *Liquor Hepatis Purificatus* Parenteral Solution of Liver

0.2 cc. equals 1 unit (injectable)

2 *Extractum Hepatis* Dry Liver Extract
50 capsules (25 gm.) equal 1 unit (oral)

Carroll Dunham Smith Pharmacal Co., Orange, New Jersey

Liquor Hepatis Purificatus Parenteral Solution of Liver

In the following dilutions

(a) 0.1 cc. equals 1 unit (injectable)

(b) 0.2 cc. equals 1 unit (injectable)

Chappel Laboratories, Rockford, Illinois

1 *Liquor Hepatis Purificatus* Parenteral Solution of Liver

25 cc. equal 1 unit (injectable)

2 *Liquor Hepatis* Liquid Extract of Liver
60 cc. equal 1 unit (oral)

Pratt. He graduated from New York University in 1884 and went to Winsted in February, 1885, to begin the practice of medicine. Named a director of Litchfield County Hospital when it was founded, he had served in that capacity since that time and was a member of both the medical and surgical staffs. He was visiting physician at the William L. Gilbert Home for forty five years. He was a member of the county and national medical societies, Litchfield County University Club and the Second Congregational Church, and a trustee of the Gilbert School and Gilbert Home. He leaves his widow, Elizabeth (Alvord) Pratt, a son, Henry G Pratt, a sister, Miss Ella Pratt, and two grandchildren, Charlotte and Margaret Pratt, all of Winsted.

TUBERCULOSIS BOOKLETS

Two booklets on tuberculosis, one for patients and the other for the "doctor of the future," will be made available this spring by the National Tuberculosis Association and its affiliated groups throughout the country to senior students in Grade A medical schools. Dr Kendall Emerson, managing director of the National Tuberculosis Association, has announced that this is part of the service of the tuberculosis groups to carry on their educational activities among the physicians, as well as among the general public.

In Massachusetts the schools receiving this service are Harvard Medical School, Tufts College Medical School and Boston University School of Medicine.

"To the credit of the American doctor," the booklet for students says, "the record shows that he has from the beginning of the organized fight against tuberculosis generously joined hands with the nonmedical crusader, fully agreeing with him that tuberculosis is not merely a disease of certain tissues but a social problem of first magnitude. This fine record should forever silence the criticism that doctors' interests are too narrowly limited to sick organs."

In its message to the students, the National Tuberculosis Association says, "The hope of eradicating tuberculosis lies in the hands of the doctors of tomorrow."

What You Should Know About Tuberculosis is the title of the booklet written for the patient. It is an interpretative booklet, offered as an aid to the physician in guiding his patient. Its tone is optimistic, and the language is simple.

ANNIVERSARY MEETING OF THE MEDICAL SERVICE, PETER BENT BRIGHAM HOSPITAL

An anniversary meeting in celebration of twenty five years work of the Medical Service of the Peter Bent Brigham Hospital was held in the amphitheater of the hospital on March 31.

At the opening of this department in 1913, Dr Henry A. Christian was physician in-chief, as he is now. The others on the staff at that time were as follows: Channing Frothingham, Jr., physician, Francis W. Peabody, resident physician, I. Chandler Walker, assistant resident physician, Reginald Fitz, house officer in charge of O. D. D., Roger P. Dawson, senior house officer, Wilson G. Smilie, junior house officer, Warren R. Sisson, sub-junior house officer, and Frances Burnham Myles, head nurse, Ward F.

The program included a presentation of three of the first four cases admitted to the service and a talk by Dr Christian on "Certain Concepts of Bright's Disease Based on Twenty Five Years Experience at the Peter Bent Brigham Hospital."

CORRESPONDENCE

LIVER PREPARATIONS CONFORMING TO U.S.P. STANDARDS

To the Editor When liver and stomach preparations were admitted to the *U.S. Pharmacopoeia*, Eleventh Edition, it was recognized that these products presented a different problem, from the viewpoint of standardization, than any question previously before the Committee of Revision.

As no ordinary methods for standardization or testing were available, an advisory board, made up of specialists in the treatment of anemia, was appointed. This board established methods for determining the value of anti-anemia products, and the basis for a U.S.P. "unit of potency." It also issued forms for reporting evidence of clinical value and announced regulations for indicating the potency of U.S.P. products and for the wording of the labels.

On the invitation of the board, a large number of clinical reports were submitted by manufacturers in evidence of the value of their products, and the board, after reviewing these records, herewith submits its conclusions. This first report lists the products which have been approved up to this time as complying with the U.S.P. specifications and the firms authorized to sell or distribute them.

As is probably generally known, only a relatively small group of manufacturers have provided the necessary hospital facilities for checking the clinical value of anti-anemia products as required by the board, and several of these distribute their products through the medium of other pharmaceutical firms.

Having been supplied with adequate clinical evidence of the efficiency of a manufacturer's product and having accepted it as U.S.P. grade with a specific dose, the board, on request, has also authorized the distribution of some of these approved products by other firms when the firms have given assurance that their handling of the products will in no way alter their quality or potency. No doubt the board will later report additional approved preparations and firms.

E. FULLERTON COOK, *Chairman,*
Committee of Revision.

43rd Street and Woodland Avenue,
Philadelphia, Pennsylvania.

* * *

REPORT ON LIVER PRODUCTS BY THE UNITED STATES PHARMACOPOEIA ANTI ANEMIA PREPARATIONS ADVISORY BOARD

The standardization of products for the treatment of pernicious anemia is defined for the first time by the Eleventh Revision of the *U.S. Pharmacopoeia* as follows: "Liver, stomach and other preparations used for this purpose, to be recognized as meeting the specifications of this *Pharmacopoeia* must be approved by the U.S.P. Anti-anemia Preparations Advisory Board. Approved products must have complied with the following specifications: (1) there shall have been submitted from time to time, as requested by the board, satisfactory clinical data from treatment, with the product in question, of cases of Addisonian pernicious anemia, (2) the clinical data submitted shall satisfy the U.S.P. Anti-anemia Preparations Advisory Board that the administration of the material in question, as prepared from liver or stomach, can produce a satisfactory result in the dose given."

In accordance with this requirement, the U.S.P. Anti-anemia Preparations Advisory Board has considered data submitted by various pharmaceutical companies. In each

Ravmer Pharmacal Co., Philadelphia, Pennsylvania
Liquor Hepatus Purificatus. Parenteral Solution of Liver
0.1 cc. equals 1 unit (injectable)

William H. Rorer, Inc., Philadelphia, Pennsylvania
Liquor Hepatus Purificatus. Parenteral Solution of Liver
0.2 cc. equals 1 unit (injectable)

Leonard A. Seltzer Company, Detroit, Michigan
1 Extractum Hepatus. Dry Liver Extract.
50 capsules (25 gm.) equal 1 unit (oral)
2. Liquor Hepatus Purificatus. Parenteral Solution of Liver
0.1 cc. equals 1 unit (injectable)

Sharp and Dohme, Inc., Philadelphia, Pennsylvania
Extractum Hepatus. Dry Liver Extract.
(a) 50 capsules (25 gm.) equal 1 unit (oral)
(b) 5 vials (25 gm.) equal 1 unit (oral)

G. H. Sherman, M.D., Inc., Detroit, Michigan
Liquor Hepatus Purificatus. Parenteral Solution of Liver
0.2 cc. equals 1 unit (injectable)

The Smith Dorsey Company, Lincoln, Nebraska
1 Extractum Hepatus. Dry Liver Extract.
50 capsules (25 gm.) equal 1 unit (oral)
2. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 0.1 cc. equals 1 unit (injectable)
(b) 0.2 cc. equals 1 unit (injectable)

United Drug Co., Boston, Massachusetts
Extractum Hepatus. Dry Liver Extract.
50 capsules (25 gm.) equal 1 unit (oral)

U. S. Standard Products Company, Woodworth, Wisconsin
1 Extractum Hepatus. Dry Liver Extract.
50 capsules (25 gm.) equal 1 unit (oral)
2. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 0.1 cc. equals 1 unit (injectable)
(b) 0.2 cc. equals 1 unit (injectable)

The Upjohn Company, Kalamazoo, Michigan
1 Extractum Hepatus. Dry Liver Extract.
50 capsules (25 gm.) equal 1 unit (oral)
2. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 0.1 cc. equals 1 unit (injectable)
(b) 0.2 cc. equals 1 unit (injectable)

Valentine Meat Juice Company, Richmond, Virginia
1 Liquor Hepatus. Liquid Extract of Liver
45 cc. equal 1 unit (oral)
2. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 1.0 cc. equals 1 unit (injectable)
(b) 1.5 cc. equal 1 unit (injectable)

The Warren Teed Products Company, Columbus, Ohio
Extractum Hepatus. Dry Liver Extract.
50 capsules (25 gm.) equal 1 unit (oral)

Western Research Laboratories, Denver, Colorado
Liquor Hepatus Purificatus. Parenteral Solution of Liver
0.4 cc. equals 1 unit (injectable)

The Wilson Laboratories, Chicago, Illinois
1 Extractum Hepatus. Dry Liver Extract.
(a) 50 capsules (25 gm.) equal 1 unit (oral)
(b) 5 vials (25 gm.) equal 1 unit (oral)
2. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 0.1 cc. equals 1 unit (injectable)
(b) 0.2 cc. equals 1 unit (injectable)
(c) 0.3 cc. equals 1 unit (injectable)
(d) 0.4 cc. equals 1 unit (injectable)

Winthrop Chemical Company, New York, New York
Liquor Hepatus Purificatus. Parenteral Solution of Liver
0.1 cc. equals 1 unit (injectable)

The Zemmer Company, Pittsburgh, Pennsylvania
1 Liquor Hepatus. Liquid Extract of Liver
45 cc. equal 1 unit (oral)
2. Extractum Hepatus. Dry Liver Extract.
75 capsules (25 gm.) equal 1 unit (oral)
3. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 0.4 cc. equals 1 unit (injectable)
(b) 0.1 cc. equals 1 unit (injectable)

The board will, as occasion arises, issue supplementary announcements either as a revaluation of the above products based upon new clinical data or to make a report upon new products which are submitted.

NOTICES

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Thursday, April 21, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), at 8:15 p. m.

PROGRAM

Adrenalin Sensitivity in Hyperthyroidism. Dr. Emil Goetsch, professor of surgery, Long Island College of Medicine.

The Value of Antitoxin in Scarlet Fever. Dr. Francis G. Blake, Sterling Professor of Medicine, Yale University School of Medicine.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Wednesday, April 20, at 12 o'clock noon. *Note change of day and date.*

Dr. Allan M. Butler and Dr. David L. Lionberger will discuss Principles and Proposals.

All physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

- Chemical Works of Gedeon Richter, Inc., Budapest, Hungary
Liquor Hepatus Purificatus Parenteral Solution of Liver
2 cc. equal 1 unit (injectable)

The Zemmer Company, Pittsburgh, Pennsylvania

1. Liquor Hepatus. Liquid Extract of Liver
45 cc. equal 1 unit (oral)
2. Extractum Hepatus. Dry Liver Extract.
75 capsules (25 gm.) equal 1 unit (oral)
3. Liquor Hepatus Purificatus. Parenteral Solution of Liver
In the following dilutions
(a) 0.4 cc. equals 1 unit (injectable)
(b) 0.1 cc. equals 1 unit (injectable)

The board will, as occasion arises, issue supplementary announcements either as a revaluation of the above products based upon new clinical data or to make a report upon new products which are submitted.

NOTICES

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Thursday, April 21, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), at 8:15 p. m.

PROGRAM

Adrenalin Sensitivity in Hyperthyroidism. Dr. Emil Goetsch, professor of surgery, Long Island College of Medicine.

The Value of Antitoxin in Scarlet Fever. Dr. Francis G. Blake, Sterling Professor of Medicine, Yale University School of Medicine.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Wednesday April 20, at 12 o'clock noon. *Note change of day and date*

Dr. Allan M. Butler and Dr. David L. Lionberger will discuss Principles and Proposals.

All physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

COURSE IN OCCUPATIONAL DERMATOSES

During May, 1938, a course in occupational dermatoses will be given under the auspices of the Harvard School of Public Health. Lectures will be given on the clinical manifestations, aspects, and so forth. Clinics will be held at the Massachusetts General Hospital, and at the offices of various insurance companies. Visits to some of the more important factories will be arranged, so that students may study industrial processes and preventive measures. The number of students will be limited to ten. Further information and registration blanks may be obtained from the Dean of the Harvard School of Public Health, 25 Shattuck Street, Boston, Mass.

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve-thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high voltage x ray. Physicians are welcome to visit this clinic and bring patients to the clinic for diagnosis.

BOSTON CITY HOSPITAL

The monthly conference of clinical pathology will be held at the Boston City Hospital on Wednesday, April 13, at 12 o'clock noon, in the pathological amphitheater.

JOSEPH E. HALLISEY, M.D., *Secretary,*
Medical Staff.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, APRIL 11

TUESDAY APRIL 12

- *9 10 a m Boston Dispensary Vitamin A Deficiency in Adults.
Dr Harold J. Jeghers
- *10 a m 12.30 p m Tumor clinic Boston Dispensary

WEDNESDAY APRIL 13

- *9 10 a m Boston Dispensary Hospital case presentation Dr S J Thannhauser
- *12 m Clinicopathological conference. Children's Hospital amphitheater
- 12 m Boston City Hospital pathological amphitheater Monthly conference of clinical pathology

THURSDAY APRIL 14

- 8 30-9 30 a m Exchange visit, surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals, held this week at the Children's Hospital
- *9 10 a m Boston Dispensary Transurethral Prostatic Resection
Dr P N Papas and Dr Harold A Chamberlin.

FRIDAY APRIL 15

- *9 10 a m Boston Dispensary Acid Base Balance in Health and Disease. Dr John H Talbott.
- *10 a m 12.30 p m Tumor clinic Boston Dispensary
- 12 m Clinical meeting of the children's medical service, Massachusetts General Hospital Ether Dome.

SATURDAY APRIL 16

- *9 10 a m Boston Dispensary Hospital case presentation. Dr Thannhauser
- *10 a m 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

BOOK REVIEWS

Short Years The life and letters of John Bruce MacCallum M.D. 1876-1906 Archibald Malloch. 343 pp Chicago Normandie House, 1938 \$3.50

Dr Malloch has interspersed in this fascinating narrative of the life of one of the most promising young scientists that American medicine has produced, selections from his voluminous correspondence, and memories which appear in his notebooks. With this intimate picture of MacCallum's intellectual development is an account of his many valuable contributions based upon his studies in embryology, histology, physiology and pharmacology, many of which were made during his medical school career, and all within the period between 1892 and 1906. Paralleling this scientific activity in point of time and equaling it in literary interest is a small but select group of prose and poetic writings reflecting a philosophy of life uncommon to the pure scientist.

There seems to have been something imparted to the students in the Canadian schools that fostered qualities in them that we have been taught to expect and have come so much to admire—a breadth of view and an imaginative insight accentuating the keenly scientific temperament. We have only to recall Sir William Osler and Jack McCrae, not to mention Archibald Malloch, himself, the author of this memoir.

Osler's earlier years find their counterpart in MacCallum's early youth. Both were intensely interested in natural history and were meticulously accurate in observation and the recording of their facts. In his struggle with the disease which from the very beginning of his career

fastened itself upon him, one is reminded of Robert Louis Stevenson, and as with him, so with MacCallum, the reader is torn between admiration for the fortitude with which he bore his affliction and the variety and extent of his accomplishments. It is this that constitutes one of the principal charms of this delightful narrative.

Born in Dunnville, Ontario, in 1876, receiving his preliminary education at home and his collegiate training at the University of Toronto, he came under the influence of Mall, Osler, Welch and the remarkable group of teachers at Johns Hopkins in 1896. Owing to the condition of his health he was obliged to seek for occupation in a climate suited to his physical infirmities. For a time he was in practice in Denver and then took a position in the University of California with Professor Loeb, it was there that the rest of his life was passed and much of his scientific work was accomplished, subject to numerous interruptions because of exacerbations of his tuberculosis. It was there, also, that death overtook him, suddenly, in 1906, terminating a career of great promise just as he was entering upon his thirtieth year.

This book should be a stimulus to every medical man and for that matter to everyone for whom science and the humanities hold any appeal.

Mental Therapy Studies in fifty cases Louis S. London.

Vol. 1 and 2 1201 pp New York Covici, Friede, Publishers, 1937 \$12.50

These two volumes are an extensive treatise on psychoanalysis illustrated by fifty detailed case histories which are reported in a clear and interesting style and with a serious scientific approach. The reviewer agrees with the author's statement that psychiatry and psychoanalysis are interwoven, an analyst without a knowledge of psychiatry is compared with an internist who does not know pathology, or a surgeon who is ignorant of anatomy.

At first the author had a Freudian analytic training, but later he worked with Stekel on dream analysis and investigated his active technique. Many of the analyses in this book are carried out by means of dream interpretation, the dreams are symbolically interpreted and the author, under Stekel's influence, makes dream symbolism the center not only of dream investigation but also of the technique of psychoanalysis. By this progressive dream analysis and an active intervention in the life of the patient, Stekel shortened the time required, as he believed that lengthy analyses were undesirable. The reviewer feels that this kind of analysis is merely a superimposed intellectual interpretation, as the complete working through of the neuronic conflicts requires a longer time. It is true that short analyses may relieve neuronic symptoms, but they do not eliminate the unconscious roots of the neurosis. However, in fairness to the author, it must be remembered that he states on page 277 of the first volume that dreams cannot be analyzed according to a stereotyped symbolism, the free associations of the patient must be connected to the manifest dream content before the cryptic meaning of the dream can be solved. Many of the author's analyses are of considerable length.

The book is divided into six parts and discusses, in turn, metapsychology, psychosexual psychology and pathology, the various neuroses, sexual perversions, and psychoses. The author believes that much can be done for schizophrenia if the analysis is begun in the early stages of the disease but the analytic therapy is fraught with great difficulties due to the incomplete transference.

In the chapter 'Psychosexual Pathology of the Sexual Instinct', the author develops a theory which involves "traumatization of the libido. This trauma liberates

the components of homosexuality, perversion and narcissism. It must be pointed out that this viewpoint is not new, as it is generally admitted that the libido is always traumatized in anxiety situations. Furthermore, he interprets narcissism as abnormal, whereas it is generally accepted that narcissism is not a perversion but exists in every living creature.

These volumes give the impression that more importance is attached to the analytic material and dream symbolism than to the usual procedure of the dynamic interpretation of the analytic situation, the latter is always indicated, but perhaps too briefly.

A Pediatrician in Search of Mental Hygiene Bronson Crothers 271 pp New York The Commonwealth Fund, 1937 \$2.00

This book, which for the purpose of clarity and completeness, has been conveniently divided into three sections, represents a thorough and careful study of the present confused positions of the pediatrician, psychiatrist, psychologist and social worker in the field of mental hygiene, and offers a tentative plan whereby an intelligent and practical solution may be evolved for the benefit of the patient and to the satisfaction of those concerned. As the author states he is not interested 'in perfecting a blend of the various virtues of each, nor in supervising a 'job analysis,' but in discovering ways of co-operation between them, which will enrich the knowledge of the pediatrician and contribute to the health of the child.' Since the field of pediatrics has progressively broadened, it is natural that mental hygiene should at least be recognized by the pediatrician, but at the same time the pediatrician should realize that neither previous training nor time qualifies him to be the director of such an organized unit. His position should be that of adviser to the group and to the parents. If such an arrangement could be reached, both the psychiatrist and the pediatrician would be in a better position to understand the scope and interrelation of their respective work. Dr Crothers stresses the importance of the pediatrician's principal duty, which is the treatment of organic diseases as they occur in children and not the practice of psychiatry. The importance and necessity of an intern's thorough knowledge of these organic disturbances is also discussed, but at the same time he points out how a competently directed clinic conducted in a children's hospital can give both the student and the intern adequate training to appreciate the mental as well as the physical aspect of the child. The entire volume is written in the frank and straightforward manner so characteristic of the author, and should prove of value to all who read it.

The Physician's Business. Practical and economic aspects of medicine George D Wolf 384 pp Philadelphia, London, New York and Montreal J B Lippincott Company, 1938 \$5.00

This book is an interesting compilation of the ethical principles governing medical practice, together with associated problems which may be studied with profit by all groups of physicians, and especially by those students who are about to graduate from medical schools, because it depicts the responsibilities and opportunities facing the hospital intern and his subsequent years of practice.

Adequate space is devoted to medical economics and the practitioner's financial problems with appropriate advice as to ways and means by which to secure material success.

Although some space is given to a discussion of comparatively simple household problems, which have little to do with the practice of medicine, the observations and advice given furnish interesting reading which will be appreciated by many.

The book closes with a chapter devoted to the "Trends in Medical Practice," with the associated controversies before the public and the profession, but without a solution of the questions under discussion.

This volume contains a great deal of useful information and sound advice which warrants careful reading.

Sir Kenelm Digby. Writer, bibliophile and protagonist of William Harvey John F Fulton 75 pp New York Peter and Katharine Oliver, 1937 \$5.00

An exhibit of works by and about Sir Kenelm Digby, largely from the collection of the author, was shown at the Grolier Club in New York City in April and May, 1937. As an introduction to the demonstration of this superb collection, Professor Fulton has written an explanation, including a brief life of Digby, an estimation of his character, and an interpretation of the value of his work to medicine. Digby's life was an exceedingly dramatic one and he lived in a time which was marked by extreme activity. Digby is known as a collector of books, a pirate in the Mediterranean, a famous lover, and a protagonist of William Harvey. Although Digby's physiology was mainly Galenical, he accepted Harvey and attempted to harmonize the new ideas about the circulation of the blood with a well systematized scheme of bodily function. Digby was also in close touch with Descartes during his years in Paris and it seems probable that Digby's ideas in regard to reflex action came directly from Descartes. Digby must, therefore, be considered as one of the early supporters of the modern conception of the nervous system.

Professor Fulton feels that Digby's scientific life has been neglected. There has been much written about his position in philosophy, his powerful influence as a patron of letters and his extraordinary gift as a letter writer, but few have noticed his relations with William Harvey or with Descartes.

This book, from a private press, is beautifully gotten up, with superb illustrations and a most pleasing type of print as well as cover. In contents, as well as in appearance, it is a choice item and the individual must be considered fortunate who owns one of the three hundred copies which have been printed.

A Textbook of Ophthalmology Sanford R. Gifford 492 pp Philadelphia and London W B Saunders Company, 1938 \$4.00

This textbook was written for the use of the medical student or the general practitioner making his first contact with the field of ophthalmology. For the beginner, it is desirable that a text be interesting, lucid in expression and informative in illustration. Gifford's text meets these requirements, and it shows evidence of wisdom in deciding what to omit as well as what to include for the beginner. Of the 492 pages of the text, 62 pages are used to outline methods of examination of the eye, and 30 pages to index the contents.

For the purpose for which it was written, Gifford's text may be regarded as a classic. Its effectiveness is enhanced by 249 well-executed illustrations, and by 10 color plates.

NUMBER 15

HETEROTOPIC GASTRIC MUCOSA

ARTHUR R. KIMPTON, M.D.,* AND A. REYNOLDS CRANE, M.D.†

BOSTON

HETEROTOPIC gastric mucosa in the small intestine is extremely rare except for its occurrence in remnants of the omphalomesenteric duct (Meckel's diverticulum). In the literature we have been able to find only 3 reported cases of ectopic gastric mucosa in the small intestine below the duodenum that were not associated with remnants of the vitelline duct. Two of these lesions occurred in the ileum and the third was found in the first portion of the jejunum. The first case was reported in 1912 by Pondecker,¹ who found a nodule composed of gastric epithelium containing both chief and parietal cells in the ileum of a girl of nine with symptoms of ileus. In 1927 Taylor² reported the second case of ectopic gastric mucosa in the ileum of a male child seventeen months of age with ulceration and death from hemorrhage. The heterotopic epithelium in this case also contained both chief and oxyntic cells. The lesion was found to be on the mesenteric border of the ileum, which, as Taylor concluded, is evidence against its being connected with a Meckel's diverticulum. The only reported instance of gastric mucosa occurring in the jejunum that we have been able to find in the literature was recorded by Bartak³ in 1932. In his case a nodule was found protruding from the serosal surface of the first portion of the jejunum in the course of a laparotomy for gastric ulcer. Histologically the nodule was described as containing both gastric epithelium with chief and parietal cells and islands resembling pancreatic acini. The tumor involved all layers of the intestinal wall, although no specific mention is made of the condition of the overlying mucosa. In view of the rarity of this condition, and the fact that we have had the opportunity to observe a case unlike any that has been previously recorded in the literature, we report the following case.

CASE REPORT

J. B., a 7-year-old girl, was seen in consultation* by one of us (A. R. K.) because of recurrent attacks of severe paraumbilical pain associated with nausea and vomiting since the age of 3. She was born at full term after a normal pregnancy, the fifth child in a family of nine. Her weight at birth was 8¾ lb and no physical abnormalities were noted. Her parents and siblings were entirely normal, and there were no pertinent factors in her past history other than those associated with her present illness.

The first abdominal complaint occurred at the age of 3, and was manifested by severe pain about the umbilicus, not localized, and marked by a continuous ache with occasional attacks of excruciating pain causing her to cry out. After 2 or 3 hours the child vomited with relief of the pain. Similar attacks occurred subsequently from three to six times a year. They lasted from 1 to 3 days, and began during the night as frequently as during the day. Following each attack the child appeared perfectly normal except for a sense of weakness. Fever never developed during any of the attacks. The mother always gave the child a laxative, this was invariably followed by a watery defecation, but at no time were the stools abnormally dark or bloody. The attacks gradually became more frequent and severe, but no definite inducing factor was ever noted. Two years after the onset of this condition a physician was consulted for the first time and a diagnosis of intestinal worms was made. Three weeks later a second physician was consulted and for the first time an abdominal mass was palpated, the mother stated that a mass could be seen especially when the pain was severe. At this time a diagnosis of volvulus was made, the abdomen was tightly strapped with tape, and abdominal massage and shaking the child in an upside-down position by holding the feet were advised. Following this the attacks were much less frequent. One year later, because of a severe attack, the patient was referred to a hospital, where x-rays of the intestinal tract revealed nothing. During the past year she had had attacks of varying severity every 4 or 5 weeks. She was seen in consultation on June 21, 1937, having just suffered an acute attack of abdominal pain.

Physical examination was negative save for the abdomen, where an elongated tumor could be felt extending diagonally across the abdomen from left to right, being 10 or 12 cm. in length, 2 or 3 cm. in width, soft, smooth and non-tender. The center of the mass lay just beneath the umbilicus. The appearance was quite typical of intussusception. While lying quietly on the examining table the

*Surgeon-in-chief, First Surgical Service, Boston City Hospital.

†Instructor in pathology, Tufts College Medical School; first assistant to the pathologist, Mallory Institute of Pathology, Boston City Hospital.

*Patient seen in consultation with Dr. F. J. Hand at the Exeter Hospital, Exeter, New Hampshire.

child suddenly screamed, doubled up, holding her abdomen, became pallid and perspired profusely. This lasted for about 10 minutes and was followed in a few minutes by a similar attack. The abdominal tumor became very prominent through the child's thin abdominal wall, while the pain was most severe. She was given gas-oxygen inhalation until surgical relief could be obtained.

At operation, the abdomen was exposed by a left para-umbilical mid rectus incision and a large intussusception of the jejunum was found starting about 15 cm below the ligament of Treitz. The bowel was edematous but entirely viable, and the intussusception was reduced with ease. When completely reduced, a soft, dough like tumor mass was found filling the entire lumen of the jejunum 20 cm below the ligament of Treitz. This was resected without difficulty by removing 12 cm of jejunum, and a side-to-side anastomosis was done. The abdomen was closed in layers without drainage.

The immediate postoperative course was uneventful. Six months after the operation the child is healthy and has had no recurrence of her previous symptoms.

Pathological Report The gross specimen consisted of a piece of small intestine (jejunum) measuring 7 by 5 by 0.4 cm. The serosa was negative but the entire wall

Figure 1 Gross specimen showing tumor nodule and jejunum. The gross resemblance of the mucosal surface of the tumor nodule to gastric mucosa is striking. About actual size.

was thickened and edematous, although not otherwise remarkable. The mucosa in one area was redundant, measuring 3 cm. in diameter and being elevated 0.4 cm. above the surrounding tissue to form a definite tumor nodule with a broad base. There was no evidence of infiltration of the underlying tissues.

Histologic sections through the redundant portion of mucosa showed it to be composed of long mucous glands of the gastric type in some of which numerous large, round, eosinophilic parietal cells could be readily identified. At the margin of the nodule there was an abrupt transition to a mucosa of the jejunal type, with many large plicae circulares and numerous goblet cells. The tumor nodule itself lay entirely on the mucosal side of the muscularis mucosa, and the redundancy of the mucosa noted in gross examination was due entirely to the numerous gastric glands of which the tumor was composed. There were occasional mitotic figures in the epithelium, but the cells were perfectly differentiated into adult chief and parietal cells, as found in the mucosa of the stomach. The submucosa, muscularis and serosa were normal save for evident intercellular edema.

DISCUSSION

This case is essentially a typical one of intussusception, but is unusual and of interest because of the embryologic anomaly which was responsible.

Figure 2 Low-power view of junction of tumor with normal mucosa. Note the abrupt transition in the character of the epithelium, and that the gastric mucosa occurs entirely above the muscularis mucosa. Hematoxylin and eosin, 9X.

for the intussusception. The role of tumors in the production of intussusception, particularly in the adult, has been emphasized by recent investigators,^{4, 5, 6} although the association of the two

Figure 3 High power field of the tumor mucosal cells, showing large, round parietal cells (indicated by arrows). Hematoxylin and eosin, 900X.

lesions has long been recognized. Roan, in reporting a series of cases of intussusception, states that tumors are a negligible factor in children up to the age of three. Since benign tumors are much commoner than malignant ones in the small intes-

ture they predominate in any analysis of tumors causing intussusception. Nevertheless, the polypoid nature of many benign intestinal neoplasms renders them even more potent factors in the general etiology of intussusception. In all reported series the commonest types of tumors encountered are myomas and adenomas, although instances of fibroma, lipoma, hemangioma and other benign tumors are not infrequent.

The occurrence of ectopic gastric mucosa has been frequently observed in the esophagus and in vestiges of the vitelline duct. Nicholson¹ states that there is an incidence of as high as 75 per cent in the upper part of the esophagus. The frequent occurrence of gastric mucosa in Meckel's diverticulum is well known. Curd⁸ in a study of Meckel's diverticulum gives an incidence of 13 per cent in reported cases while Hudson and Koplik⁹ in a report of 32 cases found gastric mucosa in 52 per cent. The role of secretion of these gastric elements leading to ulcer and hemorrhage has been emphasized by Kleinschmidt¹⁰ and others.^{9, 11} Heterotopic gastric mucosa has been noted in the duodenum by Taylor.² Nicholson¹ in an extensive study of heteromorphoses of the alimentary tract reports elements of gastric mucosa in a cyst of the pancreas, a gall bladder, a Meckel's diverticulum and tuberculous ulcers of the colon, although these were merely based on the occurrence of gastric-like cells which did not store or produce mucin in a stainable form as do the goblet cells of the small and large bowel. Stone¹² and Nicholson¹³ reported ectopic gastric mucosa in the umbilicus, probably representing a remnant of the vitelline duct.

The reasons for the development or existence of this type of abnormality are entirely unknown, although numerous theories have been suggested. We agree with Nicholson,¹³ who concludes that the developmental heteromorphoses indicate that the original prospective potencies of cells are wider than their prospective values, and that the accidental heteromorphoses suggest that the original prospective potencies are not entirely lost during development, since they are sometimes accidentally revealed in pathologic states in old age. In other words, one must bear in mind the common origin of the intestinal epithelium and realize that each cell may differentiate in various ways. This, however, carries us no closer to the pathogenesis of such lesions, beyond removing the necessity of explaining all such findings on the basis of embryologic rests. Curd⁸ reviews the various theories of origin and development of ectopic gastric mucosa. Briefly stated, these are

(1) The presence of a substance in the intestines which stimulates the formation of intestinal mucosa, and the lack of which is necessary for the formation of gastric mucosa. This substance was thought to be bile.

(2) An inflammatory process in the endoderm during some stage of embryologic development.

(3) Misplaced fetal inclusions or rests.

(4) The rapid growth of the intestines does not allow the differentiation of cells into the gastric type, while the smaller size and slower growth of the stomach allow for complete differentiation of the stomach mucosa.

The first theory has long since been proved incorrect, and is only further disproved by our case. The theory of rapid development of the intestines is likewise ruled out by this case, since we know of no specific difference in the rate of development of the jejunum and other portions of the intestines, and since the tumor covered a fairly wide expanse of mucosal surface. In the light of our present knowledge it is impossible to conclude what mechanism governs the development of ectopic gastric mucosa. We believe that the origin lies in the potentialities of the epithelial cells of the intestinal tract, but we are unable to explain their further development along other lines of differentiation.

SUMMARY

An instance of a jejunal tumor composed of ectopic gastric mucosa and leading to intussusception is reported.

The role of tumors in the production of intussusception is briefly discussed.

The occurrence of gastric mucosa in the small intestine and the theories of its origin and development are reviewed.

The authors are indebted to Dr. G. Kenneth Mallory for his assistance in preparing the illustrations.

THE HINTON TEST

V Adult Congenital Syphilis Otherwise Undetected

AUSTIN W CHEEVER, M D *

BOSTON

IN THE days of Hutchinson and Fournier a definite diagnosis of congenital syphilis was rarely made except on unmistakable clinical evidence. When the Wassermann test came into general use, not only were such cases found to have positive reactions, but numerous others were also. Some cases of congenital syphilis were disclosed in persons who had reached adult life without its existence having been suspected. Now that experience has shown that the Wassermann test fails to detect many cases of syphilis, we know that many have continued to escape detection. It was inevitable that the advent of the Hinton test, with its greater sensitivity, should bring to light a large number of latent cases. Some of these were congenital and remained undetected until maturity, since they had shown no clinical signs.

It is always important to differentiate congenital and acquired syphilis, for the following reasons. The emotional suffering can usually be lessened by the patient's knowledge that he or she is not to blame for the disease. The care is quite different, inasmuch as congenital syphilitic adults usually require no treatment. The mate and the offspring of a congenital syphilitic will not be affected, and women may need no treatment during pregnancy. Younger siblings, under eighteen or perhaps twenty, and still within the age of congenital syphilitic accidents, may be saved from damage.

Too often the possibility of the congenital form of this disease is not thought of unless the patient exhibits marked stigmas, such as typical Hutchinsonian teeth, an active interstitial keratitis or a strikingly typical history of infant tragedies in siblings. It is true that many cases show exceedingly slight evidence of congenital syphilis, but careful study of the case will generally suffice to establish the diagnosis. Very few writers have adequately emphasized the need of considering the possibility of congenital syphilis in adults, and the necessity for intensive study of the individual for slight stigmas and of his family for corroborative evidence.

Stoll¹ called attention to this group of syphilitics some years ago, he urged physicians to make wider use of their detective abilities, to give closer consideration to stigmas, slight as well as marked, to pay more attention to family studies, and to make

an intelligent and liberal use of the Wassermann test. "Within the last few years," he said, "I have been consulted by a number of adults whose symptoms were due to prenatal syphilis, unrecognized until irreparable damage had been done." He showed that when a physician's level of suspicion was sufficiently high, he was sure to find a surprisingly large number of cases of congenital syphilis that would otherwise go unnoticed. It is well known that the seriousness of congenital syphilis tends to decrease with time from infancy when it causes many deaths, through childhood when it causes local complications, to early adult life when there is relative freedom from even local manifestations. Similarly, the blood reactions tend to become negative even when the patient is given no treatment. The Wassermann test turns negative much earlier than the Hinton, so that the latter, as would be expected, reveals a greater number of cases.

Case 1 A woman of 23 was put under treatment because of a positive Hinton reaction with a negative Wassermann reaction, found routinely. The husband's tests were negative, and the patient became increasingly depressed, worrying lest he were silently accusing her. It was at this point that I first saw her. The patient's head was well shaped and her shins were sharp, but although her teeth were apparently in good condition, minute examination showed that all four 6-year molars contained many fillings. The left upper central incisor had been jacket-crowned because it was stunted and slightly notched and did not match the others. A slight deafness was noticeable, this an aurist had diagnosed as "nerve deafness, probably syphilitic." The patient was the last of eight children, all living and well, she said that there had been no miscarriages or infant deaths and that her mother was well, but that her father had died of a "nervous breakdown." Further questioning led the patient to request a true account from her mother, when she learned that the father had died of general paresis in a state hospital. She learned also that between herself and the next older sibling there was an interval of 7 years during which the mother had three miscarriages, which she had concealed because she had known syphilis to be the cause. Neither parent had received treatment except for brief treatment of the father just before his death. These facts established a diagnosis of congenital syphilis beyond doubt, and as a result the patient's emotional attitude completely changed. Despite her age she is now being cautiously treated, since she thinks that her deafness has increased a little in the past year.

Case 2 A lawyer became aware of the similarity between the treatment for syphilis given to a client's child and that given 16 years previously to his own infant son. He immediately sought medical advice. No clinical evi-

*Instructor in dermatology Harvard Medical School assistant physician Skin Department Massachusetts General Hospital

dence of syphilis was found in him, his wife or his son, Wassermann tests were consistently negative, but Hinton tests of the wife and son were repeatedly positive. While it would be impossible to make a watertight diagnosis of congenital syphilis, the acquired form of the disease in a boy of high school age should show a positive Wassermann reaction as well as a positive Hinton. Moreover, the knowledge that his mother has syphilis decidedly strengthens the argument for the congenital form.

Case 3 A man of 25 was referred for an opinion as to the safety of marriage. He gave a history of a chancre 5 years before, which appeared 4 or 5 days after a single exposure. No dark field examination had been made but on the evidence of a positive Wassermann reaction during the first few days of the lesion, the patient had been given an intensive course of treatment for 4 years without a physical examination at any time. His Wassermann reaction became negative after the treatment, but because the Hinton reaction remained positive the physician, failing to take an up-to-date view of the situation forbade marriage. While the Hinton reaction usually becomes positive very early in the primary stage of syphilis a positive Wassermann reaction has long been known to be considerably delayed. Furthermore, in this case the circumstances should have aroused suspicion of pre-existing syphilis rather than of a recent infection.

The patient was an orphan and knew nothing of his parents, or even of the existence of brothers or sisters. Examination of the teeth showed the upper central incisors to be stunted and slightly but definitely notched, the laterals were stunted but not notched, the lower incisors were set widely apart and tended toward an oval shape in cross section, instead of being normally wide and thin. Both corneas were slightly hazy, and the shins were definitely bowed anteriorly and roughened. All these signs pointed to an unmistakable diagnosis of congenital syphilis.

Considering the time that had elapsed since the patient's infection and the amount of treatment he had received he should have been permitted to marry even with acquired syphilis. Upon being told that he had congenital syphilis, which is probably never dangerous to the mate or the offspring, he married with much more confidence, and felt much easier about having stopped treatment while the Hinton test was still positive. As congenital syphilitic patients rarely have lesions after the age of 18 or 20, it is reasonable to suppose that his treatment was largely useless, and that a small amount of much less exacting and less expensive treatment would have been better. The original lesion, by the way, was undoubtedly a herpes progenitalis, for he later showed one which he said was exactly like it.

Case 4 An Italian girl of 18, wishing to marry and have children, asked for a physical examination to determine her fitness. She showed nothing of interest except a positive Hinton and a negative Wassermann reaction. There was little or no doubt of her virginity. The history disclosed that her father came to this country alone, leaving his bride in Italy until he could afford to send for her. Subsequently three children were born, with no other pregnancies, the mother was still living and well. The father had died in an accident.

In trying to ascertain whether the patient had acquired or congenital syphilis, we examined the other siblings and found their reactions negative. The mother, however, had positive Hinton and Wassermann tests, and finally acknowledged that her husband had been very promiscuous while alone in this country. As the girl was still

within the ages between which congenital syphilitic lesions may occur, she was put on oral mercury alternated with intramuscular bismuth and fairly long rest periods. So far as a possible husband or children are concerned, there is of course no danger of infection.

Case 5 An unmarried colored girl of 14 had previously received a diagnosis of acquired syphilis on the strength of two positive Hinton reactions and a pregnancy. The Wassermann reaction was twice negative, which made it very doubtful that in a girl so young the infection was acquired, especially since her baby did not have congenital syphilis. Examination of the teeth revealed 6-year molars strongly suggestive of the mulberry type, and all incisors, upper and lower, slightly stunted and rather widely separated, though none were characteristically notched. There was also poor development of the upper alveolar process, so that the incisor teeth could not be made to meet at their cutting edges in any position of the jaw. With this evidence there was no doubt that this was a case of congenital syphilis.

Case 6 A vigorous-looking man of 26, about to undergo an extensive nasal operation, was found to have positive Hinton and negative Wassermann reactions. The operation was delayed pending an opinion as to whether treatment should be given, and if so how much, before the operation could be safely performed. Study of the patient's teeth showed four lower incisors widely spaced and almost oval in cross section, with cutting edges rather frayed out but not definitely notched. The four upper incisors were artificial, having been supplied when the patient was very young because his own incisors were frail and decayed. All the 6-year molars had been removed while he was still in grammar school. No history suggestive of gonorrhea or syphilis could be obtained. There was no evidence of any scar from a primary lesion or of adenopathy, yet there were no other physical signs pointing to congenital syphilis. The family history disclosed that the mother had had three or four miscarriages in the course of producing five children. After the miscarriages only two children were born—the patient and another boy, his senior. The latter was being cared for at the Perkins Institute for the Blind, where his illness had been diagnosed as interstitial keratitis and congenital syphilis. This evidence was sufficient to substantiate a diagnosis of congenital syphilis, and established a contraindication to treatment, because of his age.

Case 7 A woman of 62 was found to have positive Hinton and negative Wassermann reactions. The diagnosis of syphilis had been made at another institution. The patient had been led to believe that she was in a dangerously infectious condition, and came to us in a frenzy of fear for herself and for her family. It was possible at her first visit to reassure her completely, and to tell her that her case was probably one of congenital syphilis. We were brought to this conclusion by the condition of her lower incisors, which were shaped almost like matchsticks. Corroborative evidence was eventually found, in that her husband and eight grown children showed no evidence whatever of syphilis. There had been several infant tragedies among her siblings. Her father had died in an insane asylum in Austria. She did not know the diagnosis but remembered that for some months he thought he was a king or an emperor, a condition that suggests general paresis. Her physical examination was perfectly normal.

Case 8 A woman was tested on applying for a position as a nursemaid. The blood Hinton test was positive and the Wassermann test negative. On repetition the Hinton

test was positive, and the woman was refused the position before being referred to me for an opinion. Her father had died in an accident. Her mother had confessed on her deathbed that she had been very promiscuous and had got herself into "very much trouble," but the patient was too young at the time to grasp the significance of the confession. The first child was said to have had perfect eyesight and perfect teeth, and a blood Hinton test was said to have been negative. The second child lived a few weeks and then died of "measles." Our patient was the third child. She had never been well, and when she was 11 years old had serious eye trouble, as a result of which she now showed scarred corneas. She had moderately typical Hutchinsonian upper central incisors, and one perfectly typical 6-year molar of the mulberry type. The other three 6-year molars were removed early in life because of bad decay. She had been slightly deaf since grammar school days. It was unfortunate that these evidences of congenital syphilis were not observed until after the patient had been refused the position as nursemaid, since she had been no possible danger to anyone for many years.

Case 9 A routine blood test on a woman of 58 was reported negative by the Wassermann technic, positive by the Hinton. As her husband and six children gave no evidence of syphilis by history, examination or blood test, it was an easy matter to prove that her case was congenital. While in high school she had had eye trouble,

which from her accurate description after the lapse of many years was almost indubitably some form of keratitis. Her lower incisor teeth were nearly square in cross section and did not quite touch the upper ones in any position of the jaw. The upper teeth had been replaced by a denture. Just to the left of the mid line there was a small hole through the soft palate, doubtless due to a gumma, and known to have appeared when she was a child.

CONCLUSION

Hospital and private records show many such instances illustrating the advantage of the blood Hinton test in disclosing obscure cases of congenital syphilis. In adult cases the Wassermann reaction is sometimes positive, but much more commonly it has by this time become negative. It has been shown how many more cases can be detected by the Hinton test than by the Wassermann test. The question as to whether the Hinton test ever becomes spontaneously negative in these cases merits further study, but from our present knowledge it appears that this seldom occurs.

THE HINTON TEST

VI Syphilis Acquired in Childhood

AUSTIN W CHEEVER, M.D.*

BOSTON

IN an attempt to find out just what was meant by a positive Hinton test accompanied by a negative Wassermann test, we made an especially painstaking study of some cases of this type at the Massachusetts General Hospital. One of the most interesting groups, though not a large one, comprised those who as children had accidentally acquired syphilis.

In the days of promiscuous wet-nursing, infantile infections were well known. Before antiseptics and asepsis, the ritual of circumcision was not uncommonly followed by accidental syphilis, as was smallpox vaccination when the much-prized "scab" from a previous patient was used. Syphilis is accidentally acquired in childhood more frequently than is usually believed, and our ability to trace and explain such infections when the patient has reached adult life often greatly reduces his or her heartache and at times prevents family complications.

CASE REPORTS

Case 1 A routine blood test on a man of 24 showed a positive Hinton and a negative Wassermann reaction.

*Instructor in dermatology Harvard Medical School assistant physician Skin Department Massachusetts General Hospital

Both history and physical examination were without interest except for the repeatedly positive Hinton reactions. Nothing suggestive of congenital syphilis was found. Later the patient said he vaguely recalled having had some intravenous injections when he was about 8 years old. It was some months, however, before he learned from his mother that he had had a primary tonsillar lesion at that age and had received what was then considered adequate treatment.

Case 2 A married woman of 25 showed a positive Hinton reaction on a routine examination, and an absolutely negative family history. She had never been pregnant. In attempting to date the infection we asked permission to make a study of the husband, whose health was excellent. His physical examination and blood test were negative and threw no light on the problem. It was not until a few weeks later that an aunt of the patient told her that because of a primary lesion many years ago on the lower lip she had been given mercury for 3 or 4 years when of primary school age. On careful examination the scar was found, faint as such scars are on the vermilion edge, but easily defined when the lip was stretched.

Case 3 A high school girl needing tonsillectomy had a routine test which showed a positive Hinton and a negative Wassermann reaction. Here no effort had to be expended to find the facts, for the patient knew that she had had a primary lip lesion several years before. She had had regular negative Wassermann tests since that

time. However, the greater sensitivity of the Hinton had detected the infection.

Case 4 A routine Hinton test taken as part of a medical examination on a man of 50 was found to be positive, while the Wassermann reaction was negative. No history suggestive of primary or secondary syphilis was given, though the patient freely admitted unusual promiscuity before marriage. Blood tests on the wife also were reported positive by the Hinton and negative by the Wassermann test. This discovery added considerable tension to an already strained family situation. The husband anxious not to add to this misunderstanding, requested that his wife should not be bothered with too searching an inquiry. It was not until the wife had made a number of visits that she happened to smile in just the right illumination to show a faint scar on the vermilion border of her lip. Questioning as to the cause of this scar settled the matter, for she described a large sore of the lip which occurred while she was a schoolgirl and lasted a number of weeks. It was accompanied by lumps beneath the chin and followed by a rash, which gave her no discomfort. Nothing was ever done about this condition so far as she could remember. Her husband's syphilis seems to have been independent of hers.

Case 5 A routine blood test on an Italian woman of 21 was positive by the Hinton method and negative by the Wassermann. After a little questioning, it was found that she had been a patient at the hospital when she was a child.

The old record showed that she had suffered from alopecia, condylomas, very large, hard tonsils, very large "tonsillar glands" on both sides, general slight adenopathy and a fading general rash. The falling hair had been the symptom that prompted the mother to take her to the hospital. The family history showed that several older siblings had come along in quick succession. There had then been four miscarriages, followed by the birth of a living child, who had contracted a "terrible case of measles" when she was 4 weeks old. At the time of the examination the measles of this youngest child consisted of the fading remains of a rash, large liver and spleen, snuffles, and mucous patches in the mouth and about the genitals. Our patient when not at school had undertaken much of the care of this baby, and had freely kissed her on the mouth. The entire family had received adequate treatment at that time, and their Wassermann tests had been negative for several years.

With a Hinton test showing a positive reaction, we were able to account definitely for her infection.

Case 6 A man of 76, born in Vienna, was found on routine examination to have a positive Hinton reaction and a negative Wassermann. He had absent knee jerks

and Argyll Robertson pupils, but an absolutely negative spinal fluid and no other symptoms of tabes. The patient expressed surprise that the Hinton test was positive, not appreciating its sensitivity. He said the Wassermann had been negative for over 20 years. When he was about 20 his mother told him that he had had a wet nurse infection with syphilis, and that he had undergone several years of treatment with mercury. He was not given treatment.

Cases 7 8 9 Three cases seen at the Massachusetts General Hospital led us to conjecture as to the eventual discovery of positive blood reactions without corroborative evidence. One of these cases was that of a baby who had had a primary lesion on the eyelid. The second was that of her sister, a year older, who had had a primary lesion of the upper lip. No source was ever found and there was no other case of syphilis in the very large family. The third case was that of a little boy with a large primary lesion on the chin, contracted from his aunt while she was caring for him during his mother's second pregnancy.

CONCLUSIONS

Though such cases as those mentioned above do not occur frequently, they should not be forgotten when an obscure syphilitic infection must be accounted for, since it is important whenever possible to establish the innocence of the infection for the sake of the patient's emotional balance and the better understanding of the situation by the present or a future mate. It is also important from the point of view of the planning for children, for it is a well-established fact that the longer the interval between infection and pregnancy, the less chance there is of a damaged fetus.

From the point of view of treatment, it is very important to date the infection, because syphilis which is of recent origin needs attention when discovered in a person from twenty to forty years old. If, however, it can be determined that the infection occurred in childhood, thus antedating the usual age of infection in acquired syphilis by from ten to twenty years, such young people need less intensive treatment. In some instances, indeed, they need none at all, depending on the physical findings, the age of the patient and the duration of the disease. For it is gradually becoming more generally realized that it is the patient and not simply the blood test that needs treatment.

464 Beacon Street.

test was positive, and the woman was refused the position before being referred to me for an opinion. Her father had died in an accident. Her mother had confessed on her deathbed that she had been very promiscuous and had got herself into "very much trouble," but the patient was too young at the time to grasp the significance of the confession. The first child was said to have had perfect eyesight and perfect teeth, and a blood Hinton test was said to have been negative. The second child lived a few weeks and then died of measles. Our patient was the third child. She had never been well, and when she was 11 years old had serious eye trouble, as a result of which she now showed scarred corneas. She had moderately typical Hutchinsonian upper central incisors, and one perfectly typical 6-year molar of the mulberry type. The other three 6-year molars were removed early in life because of bad decay. She had been slightly deaf since grammar school days. It was unfortunate that these evidences of congenital syphilis were not observed until after the patient had been refused the position as nursemaid, since she had been no possible danger to anyone for many years.

Case 9 A routine blood test on a woman of 58 was reported negative by the Wassermann technic, positive by the Hinton. As her husband and six children gave no evidence of syphilis by history, examination or blood test, it was an easy matter to prove that her case was congenital. While in high school she had had eye trouble,

which from her accurate description after the lapse of many years was almost indubitably some form of keratitis. Her lower incisor teeth were nearly square in cross section and did not quite touch the upper ones in any position of the jaw. The upper teeth had been replaced by a denture. Just to the left of the mid line there was a small hole through the soft palate, doubtless due to a gumma, and known to have appeared when she was a child.

CONCLUSION

Hospital and private records show many such instances illustrating the advantage of the blood Hinton test in disclosing obscure cases of congenital syphilis. In adult cases the Wassermann reaction is sometimes positive, but much more commonly it has by this time become negative. It has been shown how many more cases can be detected by the Hinton test than by the Wassermann test. The question as to whether the Hinton test ever becomes spontaneously negative in these cases merits further study, but from our present knowledge it appears that this seldom occurs.

Syphilis is accidentally acquired in childhood more frequently than is usually believed, and our ability to trace and explain such infections when the patient has reached adult life often greatly reduces his or her heartache and at times prevents family complications.

CASE REPORTS

Case 1 A routine blood test on a man of 24 showed a positive Hinton and a negative Wassermann reaction.

*Instructor in dermatology, Harvard Medical School; assistant physician, Skin Department, Massachusetts General Hospital.

Both history and physical examination were without interest except for the repeatedly positive Hinton reactions. Nothing suggestive of congenital syphilis was found. Later the patient said he vaguely recalled having had some intravenous injections when he was about 8 years old. It was some months, however, before he learned from his mother that he had had a primary tonsillar lesion at that age and had received what was then considered adequate treatment.

Case 2 A married woman of 25 showed a positive Hinton reaction on a routine examination, and an absolutely negative family history. She had never been pregnant. In attempting to date the infection we asked permission to make a study of the husband, whose health was excellent. His physical examination and blood test were negative and threw no light on the problem. It was not until a few weeks later that an aunt of the patient told her that because of a primary lesion many years ago on the lower lip she had been given mercury for 3 or 4 years when of primary school age. On careful examination the scar was found, faint as such scars are on the vermilion edge, but easily defined when the lip was stretched.

Case 3 A high school girl needing tonsillectomy had a routine test which showed a positive Hinton and a negative Wassermann reaction. Here no effort had to be expended to find the facts, for the patient knew that she had had a primary lip lesion several years before. She had had regular negative Wassermann tests since that

the level of the tibial tuberosity down to within 5 cm. of the lower end of the bone. It gave the appearance of a cystic tumor or a series of cystic masses of varying sizes joined together throughout the medullary canal. The cortex varied in appearance from a marked rarefaction, and in places almost complete erosion, to dense thickening and proliferation, indicating a prolonged destructive process combined with a reparative one. The middle

outward of the cortex before the tumor finally broke through.

However, when further consideration was given to the history of a visible, palpable tumor of over 4 years duration, and when a complete physical examination failed to reveal any physical sign of any extension, either direct or metastatic, and when further x ray studies of the femora, pelvis, spine, lungs and cranium failed to show any involvement, the diagnosis of malignant tumor seemed questionable.

What bone tumor could give this extensive local involvement over a period of 4 years with no signs of involvement anywhere else? At a loss to explain these findings, we felt that a biopsy aspiration was warranted in order to justify the diagnosis of bone tumor and to establish its type. This was performed 5 days later under light nitrous-oxide anesthesia. The needle was introduced through the dome of the tumor and encountered considerable resistance, as if going through a soft, spongy,

Figure 1 General appearance of the tumor in the middle and upper thirds of left leg when the patient first presented himself for advice. Note the slight discoloration on the lower or inner aspect with tortuosity of veins over the surface of the tumor.

section seemed to be the point of greatest involvement. The lateral views illustrated more clearly the extensive involvement and changes noted in the anteroposterior view, showing a complete erosion of the cortex in practically the entire length of the upper third of the tibia, and sharply demarcating the borders of the visual tumor involving the soft parts.

Clinically and roentgenologically there immediately presented itself a differential diagnosis of a soft tissue tumor involving the bone, a medullary bone tumor of osteogenic origin arising from within and extending outward, and a tumor of periosteal origin invading, secondarily, the medullary canal. The first possibility was dismissed as entirely unlikely. The third was temporarily accepted as the more plausible, primarily because of the x ray finding on the lateral view that so much of the cortex was eroded and direct extension from this point seemed to occur. It seemed also that if the tumor had arisen primarily from within the canal, there would have been considerable, gradual widening and bowing

Figure 2. Lateral view of the leg showing the lateral involvement and the elevation of the tumor mass from the tibia.

bony substance before entering the softer portion of the mass. After withdrawal of the needle, there was profuse bleeding for a few minutes at the point of insertion.

Dr Louis P Hastings, to whom the material was submitted, reported the specimen on November 21, 1935, as follows:

"Specimen consists of about 10 cc. partially coagulated blood, scattered with minute fragments of tissue, none over 1 mm. in diameter. Fragments collected, embedded in fibrin and sectioned. Sections reveal two types of tissue, namely islands of fibroblastic proliferation with giant

PRIMARY ADAMANTINOMA OF THE TIBIA

RICHARD E. DUNNE, M.D.*

HARTFORD, CONNECTICUT

ADAMANTINOMA, a tumor of enamel origin, while not frequent, is by no means a rarity, and is frequently discussed in the literature. The tumor arises as an aberrant growth of epithelial cells, which are the prototypes of those forming the inner layer of enamel origin, the so-called ameloblasts. Tumors of this type, because of their location, are almost synonymous with tumors of the jaw, their occurrence elsewhere is extremely rare, and in fact only 6 cases could be found in the literature. Of these, the tumor in the one reported by Thoma¹ occurred in the ovary. The others were all in the tibia, so that the case reported in this paper is the sixth of primary adamantinoma of the tibia on record. Because of the rarity of this disease, and the very great extent of this particular tumor, the case was thought to be worth reporting in detail. It is of interest also because it is the only one treated by x-ray, and its very evident failure to respond to preliminary radiation is noteworthy.

The first case was reported by Fischer² in 1913 and was that of a man of thirty-seven who slipped and fell on a chair, a tumor appearing five months later. Nine months later the tumor area was resected, and on this specimen the diagnosis was made. The second case was reported eighteen years later by Baker and Hawksley.³ The patient was a man of forty-six who injured his lower leg with an iron bar, with subsequent appearance of a tumor. Ten months later a subperiosteal resection was performed, and the diagnosis was substantiated by histologic examination.

Ryrie⁴ reported a case with a history quite similar to that of the previous cases, differing, as he points out, only in the long latent period. The patient, a man of thirty-six, was kicked in the shin, and eight years later a tumor appeared on the same site. Pain and tenderness had persisted most of the intervening time. Fearing that the tumor was a sarcoma, the surgeon advised amputation, but the patient refused operation. Eight years later, or sixteen years from the time of injury, the patient again presented himself for treatment. At this time resection was performed and the diagnosis was established from the histologic structure of the removed tissue. Six months later an amputation had to be resorted to because of recurrence. A fourth case was reported in 1934 by Holden and

Gray.⁵ The fifth case, reported by Bishop⁶ in June, 1937, was that of a man of twenty-two who sustained a fracture below the knee. A tumor was found at the site of fracture one month later, two months later the bone was opened, the tumor was resected, and bone grafts were inserted. Amputation was performed two months later because of recurrence, and histologic examination proved the tumor to be an adamantinoma.

CASE REPORT

J. D., aged 32, presented himself on November 18, 1933, complaining of a large swelling at the junction of the middle and upper thirds of the left leg, of approximately 4 years' duration.

He stated that in April, 1931, he fell over an iron tool box, scraping his left shin and producing an extensive, painful abrasion and contusion of the upper half of the left leg. He was given first aid and subsequent dressings for several weeks by an attendant in the plant. It eventually healed and caused him no further discomfort. Six months later, however, he sprained his ankle in the same plant, rather severely. A fracture was suspected and the ankle was x-rayed. This time he was seen by a physician, who told him that he had no fracture, but asked him what had previously happened to his leg. The physician was informed of the earlier accident, but made no further comment.

Several months later, having changed his employment, the patient noticed a small, painless lump on his left shin, to which he paid but very little attention as it caused no trouble of any kind. During the course of the next 4 years it grew steadily but slowly, until it finally reached the size of a small orange. The patient received no medical advice or treatment during this period, and steadily played golf and baseball.

The patient sought advice in November, 1935, because his family insisted on his so doing, and because the swelling was beginning to cause pain on walking.

Examination revealed a smooth, firm, elliptical tumor covered with normal appearing skin, at the junction of the upper and middle thirds of the left leg. The superficial blood vessels over the surface of the tumor were enlarged and somewhat tortuous. A slight purplish discoloration about the size of a quarter dollar, shading off into normal appearing skin, was present in the upper inner aspect, making the skin look congested. Local temperature was not increased. The whole tumor felt firm, with a deep sense of slight fluctuation to the whole mass, and a vague feeling of bony fragments of varying size embedded in the substance. The tumor mass measured 11 cm. from its superior to its inferior border and 7 cm. in its lateral diameter, it protruded forward from the margin of the tibia about 5 cm. at its greatest height, being roughly dome shaped (Fig. 1 and 2).

An x-ray photograph (Fig. 3) taken in November, 1933, showed on anteroposterior view the entire medullary canal of the left tibia to be involved with a tumor mass from

*Visiting surgeon. St. Francis Hospital and Municipal Hospital, Hartford, Connecticut.

greater absorption and erosion of the cortex over the main tumor mass. Many of the cystic areas in the medulla had coalesced to form one large cystic mass, and the discrete cystic areas lower down in the medullary canal had become larger. In the lower third, on the lateral view the cystic areas had again eroded through the cortex.

Clinically, pain, which had been absent, had begun to appear on walking. It had steadily increased for the previous month, and very recently there had appeared a dull, throbbing pain even at rest.

Because of a very definite increase in the size of the tumor, the increasing pain, the apparently increasing destruction of normal bone, and the fear of impending spontaneous fracture, this patient finally consented to amputa-

tion. Together with the fact that all the patients were men, who are more prone to trauma of the long bones than are women, gives some support to those who believe that trauma is a factor in tumor formation.

May one not hazard a speculation? Since trauma supplies the actuating influence for repair of an injury, if the repair processes in the individual are normal, normal repair will ensue. But if an individual is afflicted with an abnormal repair process of a biochemical intracellular nature, or if an abnormal geographic distribution of cellular material happens to be present, an abnormal repair process

Figure 5. Low power photomicrograph. Note the cystic spaces surrounded by small-cell proliferation.

tion. It was performed above the knee, rather than below, because of the evident likelihood of a recurrence in the stump due to invasion of the upper end of the tibia. The pathological report after amputation, dated September 14, 1936, was as follows:

"Sections reveal a scanty, branching, connective tissue stroma supporting a cellular tumor proliferation. The latter consists of cystic spaces lined with low cylindrical epithelium, surrounded by proliferations of small oval and stellate cells. These are deeply stained and closely packed, and resemble epithelial cells of the basal type. The histologic structure is that of a typical adamantinoma. Diagnosis: adamantinoma of the tibia. (See Fig 5, 6, 7)"

The patient had an uneventful convalescence the first week. He has now been back at his business as an insurance executive for about a year. There is no sign of local recurrence in the stump, and the patient is in excellent health.

This case presents many identical features with those mentioned above. All the patients were men, ranging in age from eighteen to forty-six. There was in every case a distinct history of trauma, which had been definitely connected with the site of the tumor and its subsequent development. This, to-

Figure 6. High power photomicrograph. Cystic space lined by low-columnar epithelium surrounded by small-basal-cell-type tissue.

may ensue—in the shape of tumor formation. If trauma did not occur, neither a normal nor an abnormal repair process would be called into being, and the status quo would be retained, but when trauma does occur, some form of repair process must be set in motion.

Granted, however, that there exists an interrelation between trauma and tumor formation, we still have not explained the factors causing an abnormal repair process to develop into a highly differentiated tumor, as an adamantinoma for instance rather than an adenocarcinoma.

Fischer accepted the fetal-cell theory in discussing a possible etiology for his case. He considered that in fetal life the whole surface epithelium had multiple potentialities, including that of tooth-germ formation. This potentiality, however, became lost in early fetal life after differentiation into the more mature type of pavement epithelium. In other words, the potentiality of tooth-germ formation was limited to that period of fetal life during which

cells of the epulis type, and small fragments composed of closely packed, small, oval, deeply staining cells. The latter are uniform and without anaplasia. The former

is considered a reactive tissue common to many bone tumors, the latter is true cellular tumor tissue, but of unusual type.

'Conclusion not osteogenic sarcoma. Suggest that this unusual tumor be referred to Dr. Fred W. Stewart for study.

The specimen was forwarded for an opinion to Dr. Stewart, of the Memorial Hospital, New York City, to whom we are greatly indebted for his interest and valuable aid. Dr. Stewart reported this specimen as one of tibial adamantinoma.

Once the diagnosis was established, the question of the correct treatment presented itself. Local resection was considered. By its very nature this type of tumor lends itself to such treatment, but it was suspected that the involvement in this case was too extensive to be feasible, as practically the entire shaft, cortex and medullary canal would have to be removed, necessitating extensive bone grafts from the other tibia. Resections are possible, but are doomed to failure unless complete removal can be obtained. This left either radiation or amputation. As these tumors are exceedingly rare, no precedents exist to guide one in treating them by radiation. The only reported benefits in the radiation of jaw adamantinomas seem to have resulted from treating them lightly over a long period. This patient helped us in our decision by refusing amputation.

Consequently, deep x-ray therapy was instituted, with the following technique. One port anteriorly and one port posteriorly were used over the tumor, using 75 r per day, alternating front and back, eventually giving thirty treatments per port. These treatments, as specified, were carried on by Dr. William H. Van Strander, who reported that the patient's skin was able to stand the continued application. The treatments were instituted in January, 1936, and in March, 1936, further x-ray views were taken for comparison. No change was noted from those taken before treatment was instituted. There was no apparent regression in the tumor itself, no sign of bone hyperplasia and no increase of the tumor mass. Clinically, the tumor appeared slightly larger and a little more tense.

Figure 4 X-ray films taken three months after the completion of radiation therapy. Note the progression of the tumor.

Realizing, however, that the maximum effect from radiation could hardly be expected so soon after the completion of the course of treatment, amputation was delayed further, in hope that we might be able to observe favorable changes through x-ray films taken at frequent intervals.

Films were taken at monthly intervals, and a gradual progression was noted in the tumor with further erosion of the cortex. Films (Fig. 4) taken in June showed

have been achieved through prolonged exposures to light dosage.

The results are not comparable with those of resection, which is the treatment of choice, and should be resorted to when the tumor is first seen, provided that the involvement is not so great as to challenge its feasibility. Much grief can be saved in not attempting resection of the tumor if the involvement obviously is quite extensive. The extent is not always apparent. In 2 of the cases reported, amputation was subsequently resorted to because of failure to resect the tumor completely.

It is easy to overlook cell pockets. Amputation should provide a complete and lasting cure.

PRACTICAL PHYSICAL MEDICINE FOR CHRONIC ARTHRITIS

ROBERT T. PHILLIPS, M.D. *

BOSTON

NO THERAPY has been shown to be more consistently effective in the treatment of chronic arthritis than is physical medicine. This includes the use of heat, light, massage, exercise, hydrotherapy, electricity and occupational therapy. As various efforts to introduce a specific treatment for chronic arthritis fail, physical therapy continues to enjoy increasing favor. On the other hand attempts to apply physical medicine, with its ever-widening scope, to this disease have led to the introduction of bizarre methods of treatment, particularly in the field of electricity. It is my purpose to discuss the more fundamental aspects of physical medicine, especially with reference to their practical application to the arthritic patient.

REST AND EXERCISE

Any treatment undertaken to aid the patient with chronic arthritis will lose its effectiveness if it is not fully appreciated that these individuals are suffering from chronic physical or mental fatigue, and very likely both. Until sufficient rest has been enjoyed, treatment of whatever form is handicapped. Writing on rheumatoid arthritis, which is the form of the disease with which we are here chiefly concerned, Cecil¹ says "If these patients in the early stages of rheumatoid arthritis could be persuaded to give up work and take a rest cure for six months or a year, a much higher percentage of them would make a complete and permanent recovery." Since for most people this is impossible, it is suggested that certain definite periods be set aside each day for rest. A suitable routine requires one hour in the prone position after each meal.²

Two positions may be taken during this hour: his back in hyperextension, a pillow under the head. For the first thirty minutes the patient lies on lower back and the knees, but none under the head, the arms outstretched, and the hands raised to the head, for the purpose of encouraging better use of the diaphragm, increasing vital capacity and obtaining a freer abdominal circulation. For the second thirty minutes he turns face down, supported by a pillow placed crosswise under the abdomen. This position not only reverses the gravitational effects upon the circulation, but counteracts the tendency of the abdominal viscera to sag. Pemberton enjoins us to consider rest "not only in the limited sense which the word connotes, to the laity and the profession alike, but in that more specific sense which regards the prone position as an instrument for achieving changes in the topographical, structural, and dynamic relations within the human body."³

Rest for the involved joints is essential. Plaster splints appear to be an effective means of accomplishing this purpose. They may be used for the prevention as well as for the correction of deformities. The close relation between the orthopedic field and physical medicine in this regard is suggested by Krusen,⁴ who declares "Prevention of deformities by proper splinting is an extremely important phase of home treatment."

The importance of exercise, within the limits of the individual patient, is seldom sufficiently emphasized. Arthritics must work to overcome the tendency to develop flexion deformities. Lying, sitting, standing and walking exercises, together with those for special joint and muscle groups, are available. No matter what the degree of arthritis, the patient will find it possible to carry

*Read before the New England Society of Physical Medicine, Boston, December 1st 1935.
Instructor in medicine, Tufts College Medical School; assistant physician, Revere B. Brigham Hospital.

the tooth germs were forming, and any tumor showing adamantinomatous structure could not result from epithelial transplants of the adult or permanent epithelium, but must arise from groups of cells which had accidentally become isolated before the tooth-germ potentiality became lost.

Ryrie, while disagreeing with the fetal-cell theory, makes the interesting observation that a peculiar anatomic relation exists between the bone and the skin and subcutaneous tissue over the tibia along its shaft. The skin and subcutaneous tissue are

but they are malignant only locally and do not metastasize. In this series the tumors are known to have existed from a period of eight months, in Bishop's case, to one of sixteen years, in Ryrie's, yet all the tumors remained local in nature and yielded to either local resection or amputation. The case herein reported existed for over four years.

The differential diagnosis of this tumor is difficult to make clinically or by x-ray. As seen by x-ray, it may resemble a cystic tumor or any osteogenic or periosteal invasive tumor. The duration

Figure 7 Sagittal section of the specimen removed by amputation. The true extent of the main tumor mass can be appreciated and we can realize how difficult would have been a resection of the entire tumor. Note the tre-

mendous thickening of the cortex in all directions away from the main tumor mass. The thickened cortex contained many isolated islands of tumor tissue.

freely movable over the bone in the lateral direction, and practically fixed in the long axis, so that relatively slight trauma of the scraping and shaving variety can produce severe lacerations of the subcutaneous tissue, out of proportion to the obvious, superficial injury. A tearing away of the anchorage of the tissue to the periosteum, with damage to the periosteum and production of hematoma, may entail a long period of healing, repair and ossification, the latter process may well result in an epithelial tumor growth if some of the deeper skin appendages, such as hair follicles, become involved in the prolonged repair processes which are common in this area.

If this were so, and an adamantinoma were to result, it would argue that the potentiality of tooth-germ formation might not be entirely lost in the higher forms of pavement epithelium.

In reviewing these 6 cases, it becomes quite apparent that the tumors are slow-growing. That they are epithelial and malignant is established,

of the tumor may be of great significance, biopsy aspiration, as used in this case, may prove invaluable, but it presents some difficulties if characteristic material is not obtained. It is, however, an excellent scientific method of establishing a correct histologic diagnosis of a tumor without destroying the anatomic relations between it and the surrounding structures. A possible spread of the tumor is prevented, and its actual nature is determined before any treatment is instituted.

The treatment can be briefly stated as a choice between resection, amputation and radiation. Radiation is placed last, chiefly because so little is known about fractionating the dosage or determining its duration and strength for this particular tumor in this particular location. To the best of my knowledge, it has been used only in this case of primary adamantinoma of the tibia. The result, so far as could be observed, was disappointing. It has been used in the treatment of adamantinomas of the jaw with some success, and its best results

respect to its use, for relatively few physicians have either the knowledge or the experience to apply it wisely and effectively. Until more agreement can be found among authorities in this field, electrical apparatus should be employed for arthritis only by those who specialize in this branch of therapy.

My own experience has convinced me that the simpler and more practical forms of physical medicine can achieve for the arthritic patient all that can be expected from complicated electrical apparatus. Not long ago I was studying a group of patients who were receiving mecholyl iontophoresis. Some of them who had experienced underwater therapy in the Hubbard tank thought that the prosaic warm-water treatments had accomplished considerably more for them than did the more spectacular iontophoresis.

* * *

I believe that the type of therapy carried out for the treatment of arthritic patients at the Robert B. Brigham Hospital certainly equals, if it does

not excel, any established routine that I have observed in this country or in Europe. The significant factor in this therapy, it seems to me, is its simplicity. Every effort is made to utilize those elements of physical medicine which are practical as well as fundamental, the aim being to elevate and restore so far as possible the normal physiologic processes of the body.

out some exercises which will enable him to improve his joint function and to maintain or increase the strength of his muscles. Overhead traction, with the use of elastic leg loops, is a simple and valuable method of encouraging exercise for the lower extremities, and may be employed at home as easily as in the hospital.

HEAT

The application of heat in one form or another to patients suffering from chronic rheumatism has come down to us from ancient times, when natural thermal baths were used for this purpose. Poynton and Schlesinger⁵ state: "The principle underlying the treatment of all chronic rheumatic conditions is the same, namely, to soften[relax] the tissues by heat, and to follow this by massage and movement." The problem of supplying the heat to the joints locally is, I believe, best met by the application of hot-water fomentations. Wool is the best material to use. After being wrung out in hot water and applied to the joint, it should be covered with a large, dry towel or blanket to prevent the escape of heat. Properly employed, the application of heat once or twice a day, even to an acute joint, gives excellent results.

The effect of warm water is that of relaxation and sedation. Simple contrast baths with hot and cold water alternated are valuable as circulatory stimulants. A therapeutic pool, such as the Hubbard tank, makes possible a restoration of movement and encourages re-education of lost function. Currence,⁶ who has carefully studied underwater therapy in arthritis, outlines a method for home use consisting of two or three tub baths a week for from three to six weeks, the temperature of the water being raised from 98 to 106°F in about ten minutes. This higher level is maintained for from five to fifteen minutes. When a woolen blanket pack has been in place for two hours, the average rise in temperature is to 101.2°F. There is an increase in the leukocyte count, which averages 2600, and the metabolism and general circulation are stimulated.

The value of baths for the treatment of chronic arthritis has been proved. Their employment for therapeutic purposes in the United States is slight as compared with that in Europe. The workers there are far ahead of us in this regard, largely owing to the great number of natural mineral springs and spas scattered throughout the Continent. While we are not convinced that the amount of any particular mineral in certain waters warrants the claims made by the proprietors of various spas, it is reasonable to assume that all such resorts contribute definitely to the welfare of the arthritic.

An effective form in which to use heat is melted paraffin. It is tolerated at a temperature considerably higher than is water. The application of wax gloves may be done routinely by the patient in his home, and with a clean paintbrush the wax may be readily applied to any area. According to Krusen,⁷ it is of real value in the treatment of back pain.

Fever therapy has been used in the treatment of at least forty different diseases, and numerous papers on the subject have appeared in the past two years. The best results have been achieved in gonorrhea, chronic as well as acute. With respect to arthritis, fever therapy has proved to be almost specific for the early case of gonorrheal origin, but in chronic rheumatoid and osteoarthritis it is of doubtful value.

MASSAGE

Massage continues to hold high rank among the measures of physical medicine available to the chronic arthritic. So far as this disease is concerned, it is well to recall that the underlying principle in its application, according to Pemberton and Osgood,⁸ is aimed to achieve a betterment of blood flow and other physiologic processes, yet never to increase trauma, sensitiveness or other abnormalities which already exist.

It is probable that more arthritics benefit from massage in combination with heat than from any other form of treatment. At the same time, the promiscuous ordering of "baking and massage," so commonly seen in outpatient practice for arthritics who have withstood, as Copeman⁹ says, "the onslaughts of potassium iodide or the salicylates with out improvement," is hardly to be considered proper medical treatment. There is a definite need for physicians who treat arthritis—and that means most of us—to learn and to practice the fundamental principles of massage.

Long, smooth strokes should be used in a direction toward the heart. Gentleness is of prime importance, especially in the presence of pain. The massage should be preceded or accompanied by the application of heat. Poynton and Schlesinger⁵ have written: "There are few vocations in which technic is of more value than massage. More harm than good can be done if it is entrusted to incompetent hands."

ELECTRICITY

The possibilities for the therapeutic use of electricity are legion. That this modality is popular both with the profession and with the laity is attested by the extensive and varied equipment of this character which is used in physical medicine today. Yet it seems desirable, notwithstanding its popularity, to take a conservative position with

jaundiced. Just a few days before entry she had had diarrhea and for the past two days her bowels had not moved.

Physical examination disclosed a distended abdomen without spasm but with moderate tenderness—a picture quite consistent with the presence of a mechanical obstruction, but not suggestive of a paralytic ileus due to any widespread inflammatory process. There was some dullness in the flanks which may have been due to fluid. Pelvic and rectal examinations were negative. The fact that no mass was palpable in the abdomen and the fact that no mass could be felt on pelvic examination suggest that it could not have been a large one. An ovarian cyst six inches in diameter would ride above the true pelvis so that it could not be felt on vaginal examination, but a mass 15 cm. in diameter should easily be felt through the abdomen. I therefore conclude from the x-ray findings that the soft-tissue shadow described as lying in the posterior part of the right lower quadrant was probably a flat mass with a good lateral diameter.

The woman had a temperature of 100°F., a slight leukocytosis, a mild anemia, and a lowered serum protein, with a history of what I interpret as being fairly constant pain during the attacks. Several possibilities come to mind. She may have had attacks of appendicitis, which finally developed an abscess medial to the cecum, with adherent loops of small bowel, producing recently a definite mechanical obstruction. Another possible diagnosis is diverticulitis. The x-rays fail to mention the colon, so we do not know whether such an examination was made. The type of pain would fit in well with this diagnosis. The fact that the pain started on the left side suggests it, and moreover it is not unusual for a long loop of sigmoid to lie to the right of the midline where the soft-tissue shadow was seen in the films. On the other hand I should not expect an area of chronic diverticulitis to be visible by x-ray as a mass, unless it had perforated and formed an abscess.

I have considered the possibility of regional ileitis. The patient is rather old to have this disease, and it does not seem to me that the past history is suggestive. The x-ray finding of narrow loops of small bowel may indicate it, but I do not feel that the picture was characteristic of this disease. The narrowing in this case involved several loops of small bowel rather uniformly, and the picture did not show spasm. This woman, of course, may have had cancer, but her lack of weight loss and the fact that there are so many points to suggest an inflammatory process rather make me feel that such was not the case, despite the bleeding. The facts do not point clearly to a diagnosis, but I believe she had an inflammatory process, probably an abscess in the region of the cecum

with small bowel adherent to it, and that she was getting attacks of actual mechanical obstruction. There is, however, no reason for making a diagnosis of diverticulitis without any evidence of a colon x-ray's having been done. Judgment as to source of bleeding is impossible without the results of proctoscopic examination. The history sounds to me more like diverticulitis than anything else, and this might be put down as the most likely diagnosis, with an appendiceal abscess second. The bleeding may have been due to internal hemorrhoids, although a tumor in the bowel producing obstruction is a possibility.

I should like to see the x-ray films.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON. She was a very obese person but these films are excellent. This mass that is described was quite definite. It could be seen in both the anteroposterior and lateral views, in spite of her size. This mass was sharply defined, smooth and perfectly round, and occupied the right kidney area. It was thought to be retroperitoneal because it obliterated the outline of the psoas muscle. The right kidney outline could be seen. In the lateral view the center of the mass was nearly 5 cm. anterior to the vertebrae. The small bowel overlying the mass was ileum, and was smaller than usual, so was the right half of the colon. The motor meal, however, could not fill this portion of the bowel because of obstruction at a point in the lower jejunum. That is as far as we can go. The motor meal ended rather abruptly over the region of the left sacroiliac joint. The bowel in this area was round and smooth, but the obstruction did not have the appearance of intrinsic disease of the small bowel at this point. This is the flexure of the small bowel and the actual point of obstruction must have been in another place. At the same time it did appear to point toward the mass on the right side. Then the problem arose as to why the retroperitoneal mass would obstruct the terminal jejunum and how it could do it. Also, where was the right kidney, and since she was bleeding, was the disease primary in the small bowel?

DR. HORACE K. SOWLES. I think recurrent attacks of pain of this character are typical of carcinoma of the small bowel, but of course that is a rather uncommon disease.

PREOPERATIVE DIAGNOSES

Ovarian cyst?
Large bowel neoplasm?

DR. HAYDEN'S DIAGNOSES

Inflammatory disease in region of cecum, either from diverticulitis or appendicitis, with secondary mechanical obstruction of ileum.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24151

PRESENTATION OF CASE

A sixty-two-year-old American widow entered the hospital with the complaint of abdominal cramps and vomiting of two and a half months' duration.

For the year before entry she had occasionally noticed small amounts of bright-red blood in her stools. She was not aware of having hemorrhoids. Two and a half months before entry she began to have attacks of cramplike pain beginning in the left lower quadrant, or in both lower quadrants, and radiating upward and toward the midline. The pain was usually accompanied by abdominal distention which on occasions was very marked. She also had gaseous eructations and could obtain some relief by inducing vomiting. The attacks occurred every week or two and lasted three or four days. During the attacks the eating of food seemed to increase the distention and was accompanied by some nausea. However, it had no effect on the pain. For a short time before entry she had had attacks of severe, boring pain starting in the region of the umbilicus and going through to the back. She had no hematemesis. She had no long-standing constipation, but shortly before entry had some diarrhea, and for two days before entry her bowels had not moved and she had not passed gas by rectum. Her appetite had remained quite good and she thought that she had not lost any appreciable amount of weight. She had had no jaundice or clay-colored stools.

Her past history was otherwise essentially negative, and her family history was not contributory.

Physical examination revealed an obese woman in moderate discomfort. The heart and lungs were negative. The blood pressure was 110 systolic, 60 diastolic. The abdomen was enormously distended, moderately tender and tympanitic throughout, except in the flanks where there was dullness. There was no demonstrable fluid wave, no viscera or masses could be felt, and there was no spasm. Pelvic and rectal examinations were negative except for two large external hemorrhoidal tabs.

The temperature was 100°F, the pulse 105. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,960,000 with 70 per cent hemoglobin, and a white-cell count of 10,400

with 89 per cent polymorphonuclears. The blood Hinton test was negative. The nonprotein nitrogen of the blood was 21 mg per cent, the protein 4.7 gm. The chlorides were equivalent to 100 cc. of N/10 sodium chloride. The carbon-dioxide combining power was 66.5 vol per cent.

A gastrointestinal x-ray series showed no evidence of lesions in the esophagus, stomach or duodenum. There was marked dilatation of the upper half of the jejunum, which was filled with air and fluid. There was much delay in the passage of barium through the small intestine so that at the end of twenty-four hours there was still some present in the jejunal loops. There was a soft-tissue mass measuring 15 cm in diameter in the posterior part of the right lower abdomen. The loops of the lower part of the intestine overlying this mass appeared to be narrowed, but no definite point of obstruction was visible on the films, although it was thought to be at the edge of the mass. The mass displaced the ascending colon laterally.

A laparotomy was performed two days after entry.

DIFFERENTIAL DIAGNOSIS

DR. E. PARKER HAYDEN: The first important point in the history is the occurrence of bright red rectal bleeding at intervals for a year. The fact that the patient was not aware of having hemorrhoids means nothing, because internal hemorrhoids are not appreciable to an individual unless they appear outside the anus. This woman, therefore, may have had internal hemorrhoids which were the source of bleeding. The attacks of cramplike pain began two and a half months before entry, and their character is certainly suggestive of the presence of some type of intestinal obstruction. The pain started in the left lower quadrant, was sometimes felt in both lower quadrants, radiating upward to the midline, and was accompanied by distention on many occasions. Her vomiting, however, was induced, which suggests that the obstruction must have been low down and incomplete, or she would not have had to induce the vomiting. The attacks occurred every one or two weeks and lasted three or four days. I get an impression from the history that although she was having cramplike pain, she also had more or less constant pain which lasted several days at a time. The statement that the eating of food had no effect on the pain suggests that the pain was there most of the time. A short time before entry she had several attacks of a different type of pain, boring in character, starting at the umbilicus and radiating through to the back. This story of course remotely suggests a gallstone attack, but the location of the pain, so low down, is against it, and she had not been

ible in the small intestine. The midtransverse colon was high in position, and there were questionable adhesions in the region of the right side of the transverse colon. There was no evidence of obstruction, and no masses were visible.

A laparotomy was performed on the day of entry.

DIFFERENTIAL DIAGNOSIS

DR EDWARD L. YOUNG. When any patient comes to a physician with right lower quadrant pain a great many diagnoses must be ruled out before arriving at the final one. A recent article suggests fifty-three possibilities, but of course most of these would be ruled out very rapidly. Here we have a woman of seventy with a seven months story of abdominal pain which has shifted down to the right side. I have repeatedly stated that I believe any generalized or epigastric abdominal pain which shifts to the right lower quadrant is due to appendicitis in the vast majority of cases, so that if this original attack is correctly reported she has a lesion either in or very near the appendix and involving the peritoneum. We know that at seventy appendicitis is apt to present itself atypically, and we have to be on the alert not to miss the diagnosis unless we are dealing with an abscess.

What other possibilities must we consider? We have an "apparent mass." This suggests the possibility of a tumor of the cecum, and at her age cancer is the thing that comes to mind. We have no record of the hemoglobin and red count, but neither the story nor the examination suggests that there was the obvious anemia which is so apt to go with cancer of the cecum. The fact that she had no obstructive symptoms does not necessarily rule out cancer in this region, as our attention is generally called to it before it obstructs. An intussusception does not seem to fill the bill, although it cannot be ruled out. We would expect more vomiting and a more wave-like symptomatology, when there was spasm of the bowel in an attempt to push along the intussusception there would also be nausea and vomiting, whereas in the intermission the patient would be perfectly comfortable. We have the story of bleeding by rectum, but the rectal examination suggests only a fissure and that might account for bleeding. Ovarian cysts would seem to be ruled out by the fact that this mass is well up in the abdomen, not in the pelvis, and apparently behind the bowel. A large kidney such as the larger of two congenital cystic kidneys would seem to be out of the question because of her age and because congenital cystic kidneys almost always produce the effects of chronic nephritis, whereas she has a normal blood pressure and a normal urine.

It would seem to me that we have to make the

diagnosis which is most probable on the evidence, and that is an acute appendicitis with abscess formation. We have a story consistent with it. We have a white count which is elevated with a high percentage of polymorphonuclears. We are very sure it is not a peritonitis because after two days of peritonitis we would not be hearing normal peristalsis. Peristalsis can be present early in a peritoneal infection, but it rapidly subsides and the abdomen becomes completely silent. I do not see how I can disagree with what I assume was the hospital diagnosis, acute appendicitis with an abscess formation. I cannot rule out a cancer of the cecum, but even if it is present there is certainly sepsis as well. I do not believe that a barium enema would change the treatment even if it showed an intracecal lesion.

PREOPERATIVE DIAGNOSIS

Acute appendicitis

DR YOUNG'S DIAGNOSES

Acute appendicitis, with abscess
Cancer of the cecum, with sepsis?

ANATOMICAL DIAGNOSIS

Colloid adenocarcinoma of the cecum

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN. The reasoning that Dr. Young has presented essentially coincides with that of the hospital staff. A right rectus laparotomy was performed soon after admission, with a preliminary diagnosis of appendicitis. What the surgeon found, however, was a large cecum containing on its posterior wall a tumor measuring about 7 by 5 cm. which was fixed in the iliac fossa by extension of the tumor through the cecal wall. There was some necrosis of the tumor, and evident superimposed infection, but no evidence of perforation. The appendix was not visible, and it was felt that it was imbedded in the tumor. Because of the marked adherence of the tumor to the posterior abdominal wall, because of the condition and age of the patient, and because there had not been any obstructive symptoms, nothing more was done. A biopsy from the tumor showed colloid adenocarcinoma. The procedure that was contemplated was a transverse ileocolostomy, but it was thought too dangerous at this time.

DR YOUNG. Even in retrospect I do not see how we can change our argument or make any different diagnosis. I certainly agree with the operator in not doing anything further in the face of obvious sepsis. He knows better than anyone else whether an attempt should be made to do a radical operation at a later date.

ANATOMICAL DIAGNOSES

Carcinoma of colon invading jejunum
 Obstruction of jejunum
 Cortical cyst of right kidney
 Peritonitis, acute localized
 Abscess of abdominal wall
 Coronary sclerosis with small, nonobstructing thrombus
 Pulmonary atelectasis
 Choledocholithiasis

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY The autopsy findings were interesting and a little difficult for us to interpret. The problem of the mass in the right side was easily solved. It was the kidney with a very large cyst in it, and had nothing whatever to do with any of the patient's symptoms. The small bowel was very obviously obstructed in the region of the lower jejunum, and when we took it out we found three apparently separate polyps projecting from the mucosa. Each of these polyps, however, showed necrosis in its core, which I believe never happens in a benign polyp. All of them appeared to penetrate the bowel wall, and all connected with a fair-sized mass, about 5 cm in diameter, which lay in the mesentery. This was directly adherent to an area in the sigmoid, which was hard, firm and very much constricted. On opening the sigmoid it became obvious that the lesion was a primary carcinoma of the sigmoid. Then the question arose as to whether there were multiple polyps in the jejunum plus a cancer in the sigmoid, or whether this was all one neoplasm. Since seeing the microscopic sections and re-examining the gross specimen, I now feel quite sure it is one tumor which started as a primary cancer of the large bowel, the sigmoid, invaded the mesentery and became adherent to the jejunum, penetrated it in three separate areas and continued to develop there in polypoid fashion. It is another case where I think if barium had been given from below first, instead of from above, they might have come nearer to making the diagnosis.

DR. JOHN D. STEWART What was done at operation?

DR. MALLORY At operation this large mesenteric mass was found adherent to both sigmoid and small bowel. It was not at all clear to the operator what it was. He believed it was tumor but had no idea where it was primary. He did an anastomosis between the two loops of small bowel in order to short-circuit the obstruction there, and then did a jejunostomy. The patient died about three days after operation with localized peritonitis and some sepsis of the abdominal wall, but she was in very bad shape at the time of operation.

CASE 24152

PRESENTATION OF CASE

A seventy-year-old, white, American woman entered the hospital with the complaint of right lower quadrant pain.

She was essentially well until seven months before entry when she had an attack of pain and tenderness in her right upper quadrant, with nausea, vomiting, fever and chills. After three days the pain shifted to the right costovertebral angle and right lower quadrant. During the next four days the symptoms entirely disappeared. Two months before entry she had a similar episode which lasted for five days. However, a dull ache in the right side of her abdomen persisted up to the time of entry. Her appetite remained normal, her bowels moved regularly, and she said she had maintained her strength without marked loss of weight. However, a few days before entry she began to lose her appetite, and the night before entry she developed a constant, severe, sharp pain in her right lower quadrant which kept her awake all night. The pain was accompanied by nausea but no vomiting and was increased by motion and cough. For the two days before entry she had not had a bowel movement. For many years she had had slight bleeding from the rectum after a bowel movement, and on two occasions after rectal examinations she had involuntarily passed a small amount of blood. She was an obese woman, and for two years her physician had given her thyroid, with a gradual weight loss of 25 lb. She had had no hematemesis, jaundice or melena, except as noted above. Her past and family histories were essentially negative.

Physical examination revealed a well-developed and nourished woman who did not appear to be very ill or to be suffering much pain. The heart and lungs were negative. The blood pressure was 140 systolic, 80 diastolic. The abdomen was slightly distended, and there were tenderness and spasm in the right lower quadrant and right flank, most marked in the center of the right lower quadrant. There was an apparent mass with bowel overlying it which seemed to occupy the entire right lower quadrant and flank. Peristalsis was normal. Pelvic examination showed tenderness in the right vault. Neither the uterus nor any masses could be made out. Rectal examination was unsatisfactory because of exquisite tenderness and spasm of the sphincter. The temperature was 102°F, the pulse 116. The respirations were 25.

The urine examination was negative. The blood showed a white-cell count of 14,000, 80 per cent polymorphonuclears. A flat abdominal x-ray film showed a moderate amount of gas in the colon without distention of the colon. No gas was vis-

the latter of legislation authorizing the free sale of concentrated ethyl alcohol

Furthermore, there is evidence that the increase in deaths is largely among the poor, and there are indications that welfare money has been used in many cases for the purchase of alcohol. The combined results of the depression and unemployment, and the too easy access to cheap concentrated alcohol, are apparently responsible for a large part of the death rate

A bill (House 1044) has been introduced in the Legislature for the purpose of regulating this abnormal situation. Since alcoholism is basically a public-health problem, so considered and treated in European countries, it becomes the duty of the medical profession to exert its efforts toward the correction of this serious fault in our legislation—a fault which has resulted, since the repeal of prohibition, in an annual increase of 100 deaths over the already high death rate from this cause in the Southern Medical Examiner District of Suffolk County alone

It is hoped that physicians will write to their senators and representatives and ask for the approval of House Bill 1044, which is now before the Committee on Legal Affairs

CASE HISTORY No 67 CENTRALLY IMPLANTED PLACENTA—BLEEDING AT TERM

Mrs S., a thirty-eight-year-old multipara, entered the hospital on October 29 in labor at full term. She was having mild pains and passing more blood than is considered normal for that stage of labor.

The family history was negative for diabetes, tuberculosis, cancer and hemorrhagic disease. Her past history was negative except for whooping cough, measles and mumps. The tonsils had been removed when a child, and the appendix a few

years previously. Catamenia began at the age of eleven, became regular and of the twenty-eight-day variety after two years, and lasted five days without discomfort. Her last period was January 17, making the expected date of confinement October 27. There had been two full-term, normal deliveries, and no miscarriages. The prenatal period of each previous pregnancy had been uneventful except for a slight toxemia during the late third trimester. This pregnancy had been normal except for slight bleeding once during the seventh month and a rise in blood pressure to 140 systolic, 90 diastolic, during the last month, the latter was unaccompanied by albuminuria. A vaginal examination in the office at the seventh month revealed no cause for the bleeding, and very little importance was attached to the incident as it was slight and did not recur. Throughout her pregnancy her general physical condition had been good.

When the patient entered the hospital she was in excellent condition. Her temperature was 98°F, pulse, 88, respirations, 20, hemoglobin, 80 per cent. No complete blood count was done. In view of the fact that she was bleeding more than was normal, her husband was typed, and his blood found to be compatible.

Abdominal examination showed a large abdomen with the fetus in LOA position and the presenting part high and unengaged. The fetal heart sounds were easily heard below and to the left of the umbilicus. Under careful aseptic conditions, with the patient in the Trendelenburg position and under gas-oxygen anesthesia, a vaginal examination revealed a boggy vaginal vault and a vertex that could not be made to engage. No pulsation of the vessels was noted, but a small amount of fresh blood was seen coming from the cervix. A finger was carefully inserted through a soft multiparous os, this was followed immediately by a tremendous gush of blood. Before a vaginal packing, which had been held in readiness, could be inserted, the bleeding, which was terrifying in its proportions, had stained the drapes up to the patient's neck. The introduction of 7½ yd of vaginal packing controlled the bleeding to a large extent. Following the hemorrhage, the patient's pulse rose to 128. The placenta was felt to be lying entirely over the internal os. As the patient was not in labor and the diagnosis was complete placenta previa, abdominal cesarean section was decided upon.

While the cesarean section outfit was being prepared, the patient was transfused with 500 cc of her husband's blood by the direct method. Under gas-oxygen-ether anesthesia, a section was performed with the delivery of a full-term, normal, 8 lb baby. The placenta lay completely over the

PROTECTING OUR MINORITIES

THE people of Boston more, perhaps, than any similar group in the country, deserve congratulations on having over and surrounding them a guardianship which, like Him that watcheth over Israel, neither sleeps nor slumbers. Modern censorship has indeed derived a rich inheritance from the spirit of our Puritan ancestors, who guaranteed to all, the right to think and worship as they did themselves.

True, lapses have occurred during the intervening years, in which the spirit of tolerance has raised its ugly head and flashes of personal liberty have shot their sparks against a sturdy Victorian *ostrichism*, but these were only flashes in the pan. Totalitarianism is behind the wheel, guaranteeing to its helpless minorities that they shall not learn where babies come from, nor how

No doubt censorships have their uses, and now it has been demonstrated that even *Life* itself can be censored. The disabling facts about censorships, however, are that they create an appetite, through curiosity, for this information that is being withheld, and direct attention to what might otherwise have received only casual notice.

The magazine, *Life*, is to be congratulated on the free advertising that it has received in Boston. Every so often some play, some book or some periodical is thus benefited in the Hub of the Universe.

PROPOSED LEGISLATION AGAINST THE SALE OF ALCOHOL

MASSACHUSETTS has frequently been a leader in progressive movements for the betterment of humanity, and her legislative acts have often served as models for other states to copy. Unfortunately the wisdom responsible for this highly creditable record has occasionally been in abeyance, and regrettable results have sometimes followed such lapses. A striking example in this respect is the legislation which, on the repeal of prohibition, authorized the free sale of 95 per cent ethyl alcohol by druggists. Camouflaged by the requirement that the alcohol was to be used "for mechanical, chemical and medicinal purposes only," it is generally agreed that practically all of it so sold is used for beverage purposes. The dangers arising from its beverage use are due to failure to dilute the product properly as intoxication comes on, and to the accumulation of the alcohol in the blood and organs, notably the brain, in excessive amounts. When the alcohol content of the brain reaches 0.5 per cent the outcome is usually fatal.

As should have been expected, this legislation has resulted in a very great increase in the mortality from alcoholism. Outside of Massachusetts, statistics compiled since the repeal of prohibition record a lowering in the mortality from alcoholism throughout the country. The only significant difference between the alcohol-control methods in Massachusetts and in other states is the absence in

the latter of legislation authorizing the free sale of concentrated ethyl alcohol

Furthermore, there is evidence that the increase in deaths is largely among the poor, and there are indications that welfare money has been used in many cases for the purchase of alcohol. The combined results of the depression and unemployment, and the too easy access to cheap concentrated alcohol, are apparently responsible for a large part of the death rate.

A bill (House 1044) has been introduced in the Legislature for the purpose of regulating this abnormal situation. In *The Commonwealth* Dr. Chadwick stated "This policy is based on the thesis that the practicing physician is the keyman in the cancer control movement. It is he who will first see the cancer case, it is he who must educate his patients to detect the early signs of the disease it is he who must guide the patient to adequate therapy."

"Group study is indicated in the diagnosis of cancer and the outlining of methods of treatment of the disease for cancer is so complex a subject that the opinions of the surgeon, radiologist and pathologist, as well as that of the cancer specialist, are needed. The state aided cancer clinics in Massachusetts are prepared to furnish group diagnosis and advice on types of therapy as a consultation service for the physician."

"The lay cancer committees of the town are to be known as the Co-operative Cancer Control Committees. They will arrange meetings, preferably in small groups and invite the local physicians to discuss with them the subject of cancer."

The outstanding accomplishments of the Division of Adult Hygiene in 1937 are incorporated in the following table

	1927	1933	1934	1935	1936	1937
Cancer death rate per 100 000 population	132.0	145.1	154.1	149.0	135.0	155.1
Female cancer death rate per 100 000 population age group 20-60	118.8	115.2	120.9	111.0	111 "	
Median delay in months of patients with cancer between first symptoms and visit to physician	6.0	6.1	6.2	6.1	5.0	5.0
Percentage of patients with cancer going within one month of first symptoms to physician		12.4	15.9	18.1	15.5	18.5
Percentage of patients with cancer attending cancer clinics referred by physicians	44.8	68.3	70.5	74.0	79.9	86.3
Total individuals with cancer attending cancer clinics	302	1015	1047	1042	1262	1319
Percentage of patients with cancer alive ten years after attending cancer clinics						24.5
Number of teaching clinics	0	2	6	16	42	69
Total number of physicians attending teaching clinics		75	190	422	843	1334
Percentage of physicians sending pathologic specimens from organized Co-operative Cancer Control Committee communities				4.6		13.9
Percentage of physicians sending pathologic specimens from non organized Co-operative Cancer Control Committee communities				3.2		6.8

For many years the crude death rate from cancer has been increasing. This is due in part to improved diagnoses, in part to an aging of the population, and in part, possibly to other non-ascertained causes. In the last few years, however, this rate is becoming stationary. When women alone are considered and when the effect of the aging of the population is partially removed by considering the age group between twenty and sixty, there has been in 1935 and 1936 a decided drop in the rate. The 1937 figures are not yet available, but from the crude rate it is felt that there may be an even greater improvement in this age specific rate.

The delay between the first recognizable symptoms of the disease and the time when the patient presents him

self to a physician is one measure of the effectiveness of public education in cancer. While it is impossible to obtain such a figure from all individuals with cancer, it is believed that the sample obtained at the Massachusetts state-aided cancer clinics is sufficiently representative to warrant a more or less general statement. Between 1927 and 1935 this period of delay fluctuated in the neighborhood of 6.0 months—the highest figure being 6.5 months and the lowest 6.0 months. In 1936 it dropped to 5.0 months and had held this rate through 1937. Five months is too long a period for an individual with cancer to delay before consulting a physician, but it is a decided improvement over six and a fraction months.

Another estimate of a similar nature is the percentage of individuals who go to their physicians within the first month of recognizable symptoms. In 1933 this percentage was 12.4. In 1937 it had risen to 18.5, the highest figure since the inception of the Massachusetts Cancer Program.

More and more the physicians of Massachusetts are taking the lead in referring patients to the cancer clinics. In the early days of the movement many patients came to the clinics because of newspaper publicity, and the percentage referred by physicians was relatively small. In the first year of the clinics the physicians referred 44.8 per cent of all cancer patients attending the clinics. In 1937 this figure increased to 86.3 per cent.

The total individuals with cancer attending the clinics has steadily increased. In the first year there were 302 in 1937 there were 1319. The total visits at the cancer clinics in 1937, including new and old cancer patients as well as non-cancer patients, was 12,454. Of the new patients, about one third had cancer. Of the old patients, a much larger percentage had cancer. Many of the visits of the old patients were repeat visits of the same individuals.

Of the group of 302 cancer patients who came in 1927, 24.5 per cent were alive ten years after coming to the clinic. This does not necessarily mean that all of them were cured cases. Some of them were not, but it is felt that years of longevity may well be a measure of success in a cancer program.

Teaching clinics were not instituted until 1933. Their numbers have rapidly increased from two in the first year to sixty nine in the last. The attendance of physicians at these clinics numbered 75 in the first year and 1334 in 1937—a great increase.

Another method of measuring the influence of the Co-operative Cancer Control Committee is found in the use made of the Tumor Diagnosis Service by physicians living in communities that have been organized contrasted with those living in communities that have not been organized. In 1935, 4.6 per cent of the total number of physicians in the communities that have been organized prior to January 1, 1938, sent specimens to the Tumor Diagnosis Service. From the same communities in 1937, 13.9 per cent of the physicians made use of this service. Similar figures from the non-organized communities increased from 3.2 per cent to 6.8 per cent. It should also be pointed out that in some of the organized communities, pathological services have been set up, which would make this figure even more important. Furthermore, in 1935, some of the communities were organized and others were not organized until late in 1937. This again strengthens the importance of the difference between 4.6 per cent and 13.9 per cent.

All these figures indicate that the present program is gradually accomplishing its end. The combined efforts of the medical profession and the public are being felt and

cancer control today seems nearer than ever before (Reprinted from *Cancer Bulletin*, Massachusetts Department of Public Health, Division of Adult Hygiene, Number 57, April 1, 1938)

NOTES

Among the recipients of Guggenheim Fellowships for 1938 are the following Dr Jack H Sandground, assistant professor of tropical medicine, Harvard Medical School—to study several problems in comparative parasitology in the Dutch East Indies, Dr Clyde E Keeler, instructor in ophthalmic research, Harvard Medical School—to collect material on genetics in relation to medicine, and Dr Alfred G Marshak, research fellow, New England Deaconess Hospital—to investigate the mechanism of chromosome division, especially the nature of chromosome structure as revealed by response to treatment with x rays and with neutrons

CORRESPONDENCE

DEPARTMENT OF MENTAL DISEASES

To the Editor A comparison of the latest list of trustees of the state hospitals under the Massachusetts Department of Mental Diseases with the list of trustees given in the 1933 report of this department (Governor Curley was elected in 1934) shows that by death, resignation or failure of reappointment, the Commonwealth has lost the services of twelve doctors, namely Theodore S Bacon, Enos H. Bigelow, Theodore Chamberlain, Laurence D Chapin, Albert Evans, Channing Frothingham, Charles B Frothingham, Abraham Myerson, Allan W Rowe, Henry S Rowen, J Vincent Thuot and Frederick A Washburn

In this list are one of the leading psychiatrists, one of the leading physiological chemists and one of the leading hospital administrators in the United States and the president of the Massachusetts Medical Society. In their stead, the governors have seen fit to appoint nine laymen and three doctors, namely Jeremiah A. Greene, E. Lewis Hartnett and Michael James Shaughnessy,—excellent men,—but three men cannot take the place of twelve.

Other able citizens whose names no longer appear on the lists of trustees are the Hon William J Sullivan, Mrs Esther M Andrews, Dr Henry Lefavour, Mrs Edna W Dreyfus, Albion L. Danforth, Charles A Littlefield, Horace A Keith, Professor Richard T Fisher, Francis Prescott, Frank B Hall, Walter Channing, Walter L Stevens, Arthur B Reed, Henry K. Hyde, Miss Frances E Cheney, Professor Thomas N Carver, to name a few. Here are valuable members of the community whose services and wisdom the Commonwealth can ill afford to lose.

As is well known, Dr Overholser, former commissioner, was not reappointed. He is now superintendent of St. Elizabeth's Hospital, the great federal hospital in Washington, and professor of psychiatry at George Washington University. Dr Clarence D Barrett, assistant commissioner, resigned and now heads the Department of Mental Diseases in Michigan. Another able physician, Dr Charles S Woodall, has resigned from the Fernald State School staff to be superintendent of a hospital in Vermont. Dr James V May, who in spite of ill health was persuaded to serve as commissioner for a time after the untimely death of Dr Kline, and who is a former president of the American Psychiatric Association, was forced to resign from his position as superintendent of the Boston State Hospital, and other members of the staff of

that hospital after long years of faithful service have summarily been separated from their positions. Miss Josephine E Thurlow, recently appointed chairman of the trustees of that hospital, is now handicapped in the performance of her duties by residence in North Adams.

Unless the distribution of hospital beds in Massachusetts varies from the ratio throughout the country, the 26,000-odd beds under the control of the Department of Mental Diseases represents more than half of the hospital beds in the state of Massachusetts.

Surely, the lamentable condition in the Department of Mental Diseases should be of interest to the physicians of Massachusetts and to the Massachusetts Medical Society!

Only a feeble minded optimist can believe that politicians will stop being interested in a state department that expends more money than any other department of the State except the Department of Public Works. Nor will the morale of the service be improved by giving more power to the governor and even less power to the trustees. Already, the power of the trustees is little more than that of criticism and inspection, yet they are held responsible for malfunctioning, which they have no power to rectify.

Until politics and public health are dissociated, we physicians of Massachusetts must hang our heads in shame.

DONALD GREGG, M.D.

Wellesley, Massachusetts.

ANNUAL REGISTRATION

To the Editor In the March 17 issue of the *Journal* is a letter from Dr Richard Dutton, of Wakefield, concerning 'The Proposed Bill for Annual Registration in Massachusetts'. The letter contains, either by direct statement or by implication, so many inaccuracies that I think a supplementary statement setting forth some facts is needed. I have on another occasion suggested to Dr Dutton by letter that he refrain from making public statements if he is not informed as to their accuracy.

Dr Dutton's first statement is, "in 1936, 1937 and 1938 the State Board of Registration has made determined drives to compel the medical profession to 'trade in its permanent right to practice medicine in Massachusetts for an annual permit with varying and probably increasing restrictions'." In several respects this statement is not correct. The Board has made no "drive." Under the statute the Board may, if it sees fit, suggest to the legislature that certain changes be made in the law. The Board has limited its activity to making such recommendations as to annual registration of physicians. I have been asked again and again why the Board does not fight. Such "fight," "drive," "campaign" or other effort is outside the province of the Board, so that any victory won by Dr Dutton, for example, is a victory in which he alone is fighting.

I have a copy of House Bill 41 before me 'An Act to require annual licensing of qualified physicians'. It does not provide for the 'trading in' of a permanent right for an annual permit. It contains no reference to this 'permanent right' to which Dr Dutton refers, and no provision of this bill affects the permanent right of a physician to practice medicine except insofar as such bill becomes part of the law of the Commonwealth pertaining to the practice of medicine. For years the law has provided that any "offence against the laws of the Commonwealth relating thereto," that is, to the practice of his profession, may be grounds for revocation of a license to practice medicine.

Dr Dutton has stated on one occasion that he understood that if the Board had a grudge against a doctor it could refuse to renew his registration. The bill says that if certain specified conditions are fulfilled, the Board "shall give to each qualified registered physician a certificate." Dr Dutton's understanding is at fault. The bill is mandatory.

Dr Dutton says next The Council of the Massachusetts Medical Society has each year emphatically opposed such proposed legislation. The records of the Council however, show that in 1937 the Council at first approved such legislation and at a later meeting merely withdrew its approval. Here Dr Dutton's memory is at fault.

It is encouraging to those who are interested in the passage of this bill to learn from Dr Dutton's letter that "the Committee on Public Health of the State Legislature will probably favorably report a bill for annual registration."

Dr Dutton says next The present laws read that any physician opening an office must within two weeks present credentials and sign statements with the city or town clerk, and said clerk must transmit copy of the statement to the State Board of Registration within twenty four hours and both are subject to fines for not so doing. The law on this point, Chapter 112, Section 8, is before me. It covers nineteen lines in the statute book, so I shall not repeat it, Dr Dutton's paraphrase or abstract is inaccurate in several respects.

Dr Dutton then asks three questions and says many more might be asked. The many I cannot answer because I do not know what they are. Some kind of answer, approximately correct, can be made to the three, but will Dr Dutton specify the "other rigorous existing laws to which he refers that are not enforced?"

The specific "rigorous law concerning the nonenforcement of which Dr Dutton complains is the one of which he gives the inaccurate abstract, and to which reference has already been made. It has not been rigorously enforced because, by itself, it gives the Board so little help. Not infrequently enquiries are made concerning physicians. "Who is Dr Blank?" He is not in the directory of the American Medical Association and I do not find him in the telephone book. The reply from the Board is "He was registered by the Board in 1924, and the City Clerk reported in that year that he had opened an office in Boston. We have never heard from him since. The report from a city clerk fourteen years ago does not really help much now.

The second question is, "How do lapses affect malpractice insurance?" Here Dr Dutton is again inaccurate. What does he mean by 'lapse'? There is no lapse of registration since registration cannot lapse and so malpractice insurance cannot be affected. Also since malpractice is specified by the statute as ground for revocation of license the insurance would be of no effect against action by the Board. It must be that Dr Dutton is writing about something other than what he says.

The third question is, "Would the medical profession continue to be ruggedly independent. Have you stopped beating your wife." The answer, of course, is not merely 'Yes' or 'No'. If there is any rugged independence in the profession, it will not be affected by the bill.

It is true, I think, that in every state in which annual registration of physicians has become statutory, there have been found some persons practicing under the licenses of deceased physicians. Within two weeks I have been credibly informed concerning a man who practiced for thirty years in Massachusetts under the license of a de-

ceased physician. I intentionally omit identifying details, but the matter recently came to light after the death of this unlicensed person. It is reported that the chiropractors are making vigorous efforts against this bill. Does Dr Dutton know what his co-laborers are doing and why?

When the Board, familiar with some of the difficulties of restricting the practice of medicine to persons duly licensed, says that annual registration of physicians will be distinctly helpful in law enforcement, presumably there is something in it. One might object on the ground that it will not work, that is, it will not accomplish what it is intended to accomplish. The answer to this is the testimony from other states, the law has been successful, and some states say they do not know how they could get along without it. One might complain that he refused to be taxed for this purpose. This objection must be dealt with on its merits. I presume that Dr Dutton would refuse to drive an automobile on the ground that he did not approve of some of the uses to which the gas tax is diverted.

The reason why the annual registration of physicians, or the annual licensing of physicians, will become statutory sometime, if not this year, is because the people of Massachusetts are entitled to know what persons are licensed to practice medicine, and what persons actually are practicing medicine in this State. This information should be made available in the form of lists printed annually and kept up to date. When the people know what is involved, they will demand the information and they will get it, as they cannot do now. Any talk about the 'regimentation' of physicians, the taking away from the physician his right to use his best judgment in practice, or the 'trading in' of any permanent right to practice, on the basis of House Bill 41, is merely silly.

EARLY OPERATIONS FOR APPENDICITIS

To the Editor With the renewed interest in the treatment of appendicitis, the following account of the steps leading up to the first operations for the treatment of the disease may be of interest.

ALFRED WORCESTER, M.D.

Waltham, Massachusetts.

A half century ago when we were asked why there was more appendicitis in Waltham than in Boston our answer was that we so named our patients recoveries while elsewhere the death certificates for the same disease gave peritonitis as the cause. This though impolite was nevertheless the truth. It reminds me of what was said to me in London in 1888. I had been introduced by kind colleagues to famous British surgeons. The notes of introduction mentioned my familiarity with appendicitis. But I was astonished by the statement of my newly found friends that they had no such disease in England. Some years later one of these gentlemen postponed the coronation of Edward VII on account of the King's appendicitis. A few years later I persuaded Harvard to give him an honorary degree.

As a matter of fact Waltham is the place where the operation for appendicitis first became fashionable. And perhaps the story of what led up to this treatment of the disease will be of interest. During the spring and summer of 1883 when I was house physician at the Boston Lying in Hospital I had sad experiences with puerperal

peritonitis This tragic story I have told elsewhere (*New Eng J Med* 209 1109 1112, 1933) The pathologist at the Massachusetts General Hospital, Dr W F Whitney, kindly performed an autopsy on one of these patients The great accumulation of pus in the abdominal cavity of that poor woman made a great impression on me And later in that year, in my association with Dr E R Cutler, an autopsy which I had the misfortune to have to perform on a similar puerperal case gave the same result The next year at an autopsy on an older woman a large collection of pus was found in the right side of the abdomen Soon again one of my patients—a strong young man—died with his abdomen full of pus

My growing conviction that it would be better to have such collections of pus evacuated before rather than after death was strengthened by Dr B F D Adams, to whose practice I succeeded when he was obliged to leave Waltham for Colorado Springs He told me that if he were able to resume his practice he would employ surgical treatment in such cases Dr E R Cutler, my senior partner, had also come to the same conclusion We decided that in such cases if not allowed to employ surgery we would not continue in charge of them To Dr Cutler first came the test of our conclusion On June 20, 1886, one of his patients, a railroad conductor, after a few days' sickness, presented symptoms of an abscess in the right abdomen He consented to operation Then the question was how to get at the pus It would of course never do to make a direct attack That would violate all surgical canons And so Dr Cutler bored in from under Poupert's ligament The pus came out freely, and if there also presented a gangrenous mass, Dr Cutler failed to dislodge it But a few days afterward such an object appeared on the dressings Neither of us knew what it was We had never seen a gangrenous appendix Dr Cutler in his brief report of this case (*Boston M & S J* 70 554 556, 1889) mentions only a free discharge of faeces from the wound The man made a rapid and complete recovery

My turn came next On August 19, 1886, I was called to a case of a nine year-old girl who had just been sent home from the Massachusetts General Hospital to die Her parents were told there that the case was inoperable When I told them of my determination to continue in charge of such a case only when allowed to employ surgical treatment they naturally were at first very unwilling But two days later, on the ninth day of the disease, they consented, convinced that otherwise the child would die My operation (first reported by Dr Cutler in his article previously noted) was briefly as follows I aspirated through the loin, sucking pus flowed from the trocar Following the trocar with bistoury, dilators and then with my fingers, I found a small mass in the abscess cavity Dr Cutler insisted that I must have cut into the cecum and got hold of a lump of feces I protested this was not the case "Then pull it out, he said. Telling him it was hitched on, I asked for a double tenaculum and with this I pulled out the object Again neither of us knew what it was The child, however, made a rapid and complete recovery and is still living This was before Dr Fitz's famous pronouncement upon the cause of typhlitic abscesses The reason why Dr Cutler insisted even in his reports of these cases that the masses were merely feces is that we then knew the appendix vermiformis only as its name implies But we were making progress our patients made rapid recoveries.

In the next case of our series I was the patient I had had many previous attacks, some of them quite severe. But this time it was terrific Fortunately for me, my

classmate, Dr H A Wood, had begun his practice in Waltham, and to his unremitting care by night and day I owe in large degree my life But the surgeon who finally consented to my appeal for operation was Dr J W Elliot With Drs R H Fitz and M H Richardson in opposition, on the ground that I was too near death from general peritonitis, Dr Elliot boldly operated by direct incision over what I insisted was the seat of trouble He did not find the appendix but evacuated the pelvic abscess As this operation has been described by Dr Elliot (*Boston M & S J* 68-92 93, 1888), my own impressions would be of little value But when I read in Dr E A Codman's memoir of Dr Elliot that this operation was the first in the world where a man's abdomen was deliberately opened by a surgeon in search for the cause and relief of his peritonitis, I realized for the first time my real distinction

The next forward step in our Waltham progress toward the proper treatment was equally bold and brilliant During my convalescence Dr Cutler came to tell me about one of our neighbors who had just begun to have the same trouble I begged him to tell the man that if he would consent to immediate operation he no doubt would be saved from the suffering and danger I had just been passing through The man consented, and on December 23, 1887, Dr Cutler and Dr Wood after a direct abdominal section removed his inflamed and partially gangrenous appendix The man made an immediate recovery For Dr Cutler's modest report of this first perfect appendectomy, see his article previously noted.

With these experiences is it any wonder that we became convinced of the advisability and even the necessity of immediate operation in cases of appendicitis? But it was a long time before we Waltham men had the support of our professional brethren. Instead, we encountered their bitter opposition. In various records of medical meetings during the next few years reports may be found of discussions of Waltham's heresy, that is, of our departure from what was then held to be correct procedure. But I do not know if there was ever published a report of the meeting of the Suffolk District Medical Society at which I was hammered unmercifully The meeting was called for the discussion of the treatment of appendicitis. On the blackboard were written three questions to which the discussion should be confined The first question was, What should be the medical treatment of appendicitis? The second was, 'If surgery is employed, when should it supersede medical treatment?' The third was, 'If surgery is employed, where should the incision be made?' As a guest my turn came last. In answer to these questions, I said that there is no medical treatment for appendicitis, that the only proper treatment is surgical from the outset of the disease, and finally that the surgical incision should be, as always, over the seat of the trouble. I then exhibited eight diseased appendices which we Waltham men had removed from our patients I told them that seven of the patients had recovered, and that the eighth specimen had been taken from a dying man who begged for the operation even after I told him there was but one chance in a thousand of his survival I operated because I myself had begged so nearly in vain for operation after I had been told that I was near to death Then the storm broke. I was asked by an irate surgeon how I dared violate all surgical principles My answer was that it was because I was a coward and did not dare not to operate. Dr M H Richardson then said that he had operated fifty times on typhlitic abscesses and in none of these cases had he ever seen the appendix Then in the heat of the battle I declared that Dr Richardson by his own admission was not

competent to discuss the subject, in that he had never treated the disease but only its sequelae. This unhappily led to a breach between good friends.

Over our beer at the Tavern Club after the meeting Dr Fitz begged me to apologize to Dr Richardson, saying that I had cut him to the quick, but Dr Elliot insisted that I should not do so, for what I had said was the truth. So far as I remember Dr Elliot was my only backer at this large meeting. But after several years Dr Richardson forgave me. At the semi-centennial anniversary of the first use of ether as an anesthetic, he came to me at the

luncheon saying that he wanted to introduce me to Dr McBurney, of New York, who had become famous for his appendectomies. Dr Richardson said to him, "I want to introduce to you a man who took out the appendix before you ever heard of it." Dr McBurney asked me, "When did you first take out the appendix?" I replied, "In August, 1886. When did you first perform the operation?"

Goodness, not until 1888, or perhaps it was even 1889 that he said. After that Dr Richardson and I were even closer friends than we were before. He had by then become the foremost New England appendectomist.

ETHER-OPERATION PAINTING

To the Editor The painting, by A I Keller, of the ether operation at the Massachusetts General Hospital, October 16, 1846, which is here reproduced through the courtesy of Houghton-Mifflin Company, has appeared in many publications, and one would think that the original could be easily found. Attempts, however, to do so have failed, even though inquiries have been made at the

Massachusetts General Hospital, the Boston Museum of Fine Arts the Boston Public Library and elsewhere. Can any of our readers give this information? In addition, one would like to know something more about the circumstances under which this picture was painted.

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

To the Editor In addition to the articles enumerated in our letter of February 26 the following have been accepted

The Drug Products Co

- Hyposols Sodium Cacodylate, $\frac{1}{4}$ gr (0.048 gm.), 1 cc
- Hyposols Sodium Cacodylate, $1\frac{1}{2}$ gr (0.10 gm.), 1 cc
- Hyposols Sodium Cacodylate, 3 gr (0.194 gm.), 1 cc
- Hyposols Sodium Cacodylate, 5 gr (0.324 gm.), 1 cc
- Hyposols Sodium Cacodylate, $7\frac{1}{2}$ gr (0.5 gm.), 5 cc

Eli Lilly & Co

Sulfanilamide Tablets, $7\frac{1}{2}$ gr (0.5 gm.)

Parke, Davis & Co

Tablets Sulfanilamide, $7\frac{1}{2}$ gr (0.5 gm.)

PAUL NICHOLAS LEECH, Secretary

Chicago, Illinois.

REPORTS OF MEETINGS

TRUDEAU SOCIETY

A meeting of the Trudeau Society was held at the Beth Israel Hospital on February 24. Dr Leon A. Alley, the chairman of the meeting, introduced the speaker of the evening, Dr Evarts A. Graham, of St. Louis, whose subject was "The Problem of Bronchiogenic Carcinoma."

Dr Graham opened by stating that in his opinion all primary carcinomas of the lung are bronchiogenic in origin. He then divided bronchiogenic carcinomas into two groups: (1) squamous-cell carcinomas—a well defined group, both clinically and pathologically, (2) a large heterogeneous group of tumors including the so-called round cell carcinomas and oat-cell carcinomas, adenocarcinomas, and the recently much discussed adenomas. It was concerning this last tumor, the so-called benign adenoma of the bronchus, that Dr Graham talked in detail.

The benign adenomas arise from a bronchus and appear on bronchoscopy as smooth, round, vascular, pedunculated tumors. To the bronchoscopist it appears as if he were dealing with a benign tumor which he can completely remove. Histologic examination of these tumors reveals an encapsulated mass composed of cords of small round cells showing no mitotic figures. In the literature there is a widespread belief that they are benign in character, hence the name benign adenomas. It was the thesis of Dr Graham's talk that these should not be regarded as benign tumors, and furthermore, that they are related to the round-cell and oat-cell carcinomas and the adenocarcinomas of the lung.

The speaker then presented cases in which the diagnosis of adenoma was made at bronchoscopic examination and confirmed by biopsy, in some of the cases it was felt by the bronchoscopist that all the tumor had been removed. Opportunity for further examination of the involved lung was obtained either through pneumonectomy or autopsy. Examination showed that all the tumor had not been removed at bronchoscopy, and that in some areas the remaining tumor cells were invading blood and lymph vessels. In his series of cases of adenoma, metastases have been found in mediastinal lymph nodes, in the parietal pleura and in many distant organs, particularly the adrenals and kidneys. Hence these tumors cannot be considered to be benign, and as their histologic structure is not that of an adenoma, the term benign adenoma is a most unfortunate one.

Dr Graham then projected a series of slides to show that material closely resembling fetal mesenchyme and fetal bronchi is sometimes found in these tumors. In fact there is a startling histologic resemblance between fetal lung tissue and biopsy specimens of these adenomas. In addition, bone and cartilage are seen in these tumors. Turning to the embryologic development of the lung, he showed that in the course of normal development there are excessive numbers of bronchial anlagen, many of which normally atrophy. He then postulated that these tumors arise from bronchial anlagen which would normally atrophy but for some reason fail to do so, and suggested the term 'embryoma' as a more fitting name. Tumors arising from these anlagen would be expected to contain more than one type of tissue: connective tissue, bone and cartilage, as well as epithelial cells are found in these tumors. In Dr Graham's opinion the rare chondromas, fibromas, fibrosarcomas and lipomas have the same origin, and represent varying lines of differentiation. He suggested that in addition the round cell and oat-cell carcinomas and the adenocarcinomas have a similar origin from bronchial anlagen which have failed to atrophy.

In support of this theory, he showed that the lungs containing adenomas often have certain developmental abnormalities, such as, small accessory bronchi (in one case the lung contained ten or twelve of such bronchi), accessory lobulation, and abnormal development of fissures.

These tumors, and bronchiogenic tumors in general, are peculiar in that they often occur in young individuals. Many of the patients have a very long history of pulmonary symptoms, sometimes as long as eighteen years.

In summary, Dr Graham pointed out that the term adenoma was a very poor one, that these tumors should be regarded as potentially malignant, and that while bronchoscopic removal may be occasionally complete, more often a portion of the tumor is left behind.

The discussion was opened by Dr Edward D. Churchill, who agreed that the term, adenoma, was a poor one. He stated that he was attracted to the hypothesis that these tumors arise from embryologic defects and agreed that these tumors should be regarded as dangerous lesions. Dr Richard H. Overholt illustrated by figures from his clinic that the clinical diagnosis of carcinoma of the lung is now being made in a high percentage of cases, and that the mortality rate following pneumonectomy has now reached a surprisingly low figure, only 1 death having resulted from 11 pneumonectomies done in 1936 and 1937.

Following this a number of questions were asked of Dr Graham, who, in closing, answered as follows: (1) in the vast majority of cases fluid in the pleural cavity in cases of pulmonary carcinoma indicates pleural metastases and is a contraindication to operation, (2) it is possible to find malignant cells in pleural fluid in an appreciable percentage of cases, (3) in a case presented by Dr Henry L. Cabitt, in which an "adenoma" had been removed bronchoscopically and which now shows no evidence of tumor, he advised against an immediate pneumonectomy and favored waiting with close observation, (4) true papillomas of the bronchus do occur, but they are exceedingly rare, (5) there is no evidence that tuberculosis and bronchiectasis have any etiologic relation to pulmonary carcinoma, (6) in commenting upon a question concerning an apparent discrepancy between the results in Jackson's series of cases and his own conception of the nature of adenomas, he emphasized that he did not deny that in some cases bronchoscopic removal effects a cure, but that he did feel such an outcome is rare. He also pointed out that these tumors have the peculiar ability to form scar tissue at the point of biopsy, and that this may delude the bronchoscopist at subsequent examinations into believing no tumor is left behind.

NEW ENGLAND HEART ASSOCIATION

The regular monthly meeting of the New England Heart Association was held at the New England Deaconess Hospital on February 28. The following program was presented:

PROGNOSIS OF ADULT WOMEN WITH MITRAL STENOSIS. Burton E. Hamilton, M.D.

A group of 100 women of childbearing age, averaging twenty-nine years, with chronic rheumatic heart disease, were re-examined after an average interval of ten years. There were only 6 cases of rheumatic fever in 900 patient years. There was little evidence of a tendency for the rheumatic disease to progress, and less evidence that it tended to improve. Twenty-nine died. Seventy-four were in a favorable group when first seen, 20 per cent died. Of 26 in an unfavorable group, 54 per cent died. The mortality rate in the whole group and in all subdivisions were definitely better than that reported by Grant from a follow up of British soldiers with chronic heart disease. Among women who had uncomplicated mitral stenosis where a diastolic murmur of the aortic type appeared later, more often than not this murmur persisted. There was, however, definite evi-

dence of an inconstant diastolic murmur of the aortic type in some patients with mitral stenosis. This is a preliminary report. A report on a larger group will be made later.

THE HEART IN POSTOPERATIVE DEATHS Shields Warren, M.D.

In the period from January 1, 1927 to June 30, 1937 there were 252 postoperative deaths autopsied in this laboratory. These cases were primarily derived from the New England Deaconess, the Palmer Memorial, and the New England Baptist hospitals, although a scattering of other cases are included. These cases represent 14 per cent of the autopsies (1756) during this period.

Those cases dying within one month after operation are considered as postoperative deaths provided that the death was not due to the natural course of the condition for which the operation was done. Thus if the patient died of metastases of carcinoma of the rectum following a palliative loop colostomy, it was not considered as an operative death. Two groups of cases representing unusual surgical hazards have been excluded. These are the cases of brain surgery and of chest surgery.

Twenty-six of 252 postoperative deaths, or 10.3 per cent, were cardiac. This is the fourth most important cause, being outranked by sepsis, pulmonary embolus and pneumonia.

Naturally these fatalities occurred in old individuals. The average age was 62.6 years, the youngest patient was forty years of age, the oldest eighty-three. Postoperative cardiac death, therefore, is almost entirely a problem of the later decades. Sixteen of the patients were male, 10 female. The youngest patient dying of a cardiac death was a woman of forty years of age, dying of coronary sclerosis immediately following a hysterectomy. She was moderately obese which was undoubtedly an important factor.

The predominant lesion in this group is coronary disease. The primary disease for which operation was done ranged from renal calculus to carcinoma. Several diabetic and thyroid cases are represented.

Subacute bacterial endocarditis (due to *Streptococcus viridans*) occurred in only 1 patient, a woman of sixty-nine, dying two days after vulvectomy for carcinoma. It might be mentioned in passing that in the generally weakened condition of patients with advanced carcinoma it is not unusual to encounter early lesions of bacterial endocarditis. However, this is the only instance I have encountered where death was due to endocarditis itself rather than to the accompanying cancer.

One case of acute pericarditis occurred, developing in a sixty-two-year-old man who died eight days after a transurethral prostatectomy.

Two deaths occurred from auricular flutter, the first secondary to a congenital heart condition, the other secondary to hyperthyroidism.

Before taking up coronary occlusion in great detail I shall speak briefly of the means of recognizing coronary occlusions. The time honored method of opening the coronary artery with scissors is one that is eminently suited to destroy all evidence of any but the most clearly defined coronary occlusions. The point of the scissors will plow a path through all but the best established thrombus or atheromatous plaque, and the pressure by the blades of the scissors makes it most difficult to tell the exact nature of the lesion. As Dr. Leary has so clearly emphasized, transverse multiple sections of the coronary with a knife usually provide the most satisfactory visualization of the extent of disease present and the degree of

encroachment by atheromatous or thrombotic changes on the lumen. Even superior to this method is the beautiful radiographic technic worked out by Dr. Schlesinger, of the Beth Israel Hospital, who, by means of colored radiopaque injection masses with subsequent roentgenography and dissection, is able not only to demonstrate vascular occlusions and anastomoses, but the portions of the heart supplied by the right and left coronary vessels respectively.

The ideal method of detecting coronary lesions is that of Schlesinger, the next best multiple transection, the poorest the customary opening with scissors. It might not be amiss in this connection to remind you that the presence of demonstrable infarction of cardiac muscle is not only contingent upon coronary occlusion but is also conditioned by the time elapsed between the occlusion and death. A coronary occlusion resulting in immediate death gives no evidence of infarction. The changes that permit us to recognize infarction grossly require a period of two or more hours between cutting off the blood supply, and death. Microscopic evidence of infarction probably appears but little earlier.

If one waits for evidence of cardiac infarction before making a careful search for coronary occlusion, many cases will be missed because death is often too rapid to permit alteration in the myocardium. On the other hand the mere finding of an occlusion does not necessarily mean that it was the cause of death. Unless the occlusion occurs in a major branch it is quite possible for the myocardium to weather the storm. I have seen large numbers of old healed infarcts in a single heart.

As has been repeatedly pointed out, due to anastomotic circulation no appreciable fibrosis or degeneration of the myocardium may occur in spite of the presence of definite occlusion, particularly in the smaller branches. Gross evidence of recent infarction is present in about one quarter of the cases and in several instances both old and recent infarcts occur in the same heart.

Congestive heart failure is infrequent. Four of the 26 cardiac deaths were due to congestive failure, one a seventy-two-year-old woman who died twenty-nine days after cholecystectomy for a stone and who showed at autopsy several old and one recent infarct of the myocardium with occlusion of her left coronary, another a fifty-year-old man who died four days after a partial gastrectomy for ulcer and who showed at autopsy chronic vascular myocarditis without appreciable change in the larger vessels, another a sixty-nine-year-old man, dying two days after nephrostomy for calculus, whose heart showed chronic vascular myocarditis, and the last a sixty-nine-year-old male diabetic, dying twelve days after a Gritti-Stokes amputation for gangrene, with chronic vascular myocarditis.

When one considers that in this group of cases preoperative digitalization has not been the rule, the occurrence of only 4 congestive deaths postoperatively in ten years is rather suggestive that routine preoperative digitalization is not an essential procedure in the elderly surgical case. If coronary arteriosclerosis could be eliminated, the cardiac postoperative deaths would drop into practical obscurity.

HEART NOISES. Frank N. Allan, M.D.

A woman came for examination complaining of heart trouble of unusual nature. She had been disturbed by a noise synchronous with the heart beat which had appeared intermittently for two years. It frequently bothered her during the day, but was likely to be particularly troublesome when she was lying down at night. The

Dr Graham opened by stating that in his opinion all primary carcinomas of the lung are bronchiogenic in origin. He then divided bronchiogenic carcinomas into two groups (1) squamous-cell carcinomas—a well-defined group, both clinically and pathologically, (2) a large heterogeneous group of tumors including the so-called round-cell carcinomas and oat-cell carcinomas, adenocarcinomas, and the recently much discussed adenomas. It was concerning this last tumor, the so-called benign adenoma of the bronchus, that Dr Graham talked in detail.

The benign adenomas arise from a bronchus and appear on bronchoscopy as smooth, round, vascular, pedunculated tumors. To the bronchoscopist it appears as if he were dealing with a benign tumor which he can completely remove. Histologic examination of these tumors reveals an encapsulated mass composed of cords of small round cells showing no mitotic figures. In the literature there is a widespread belief that they are benign in character, hence the name benign adenomas. It was the thesis of Dr Graham's talk that these should not be regarded as benign tumors, and furthermore, that they are related to the round-cell and oat-cell carcinomas and the adenocarcinomas of the lung.

The speaker then presented cases in which the diagnosis of adenoma was made at bronchoscopic examination and confirmed by biopsy, in some of the cases it was felt by the bronchoscopist that all the tumor had been removed. Opportunity for further examination of the involved lung was obtained either through pneumonectomy or autopsy. Examination showed that all the tumor had not been removed at bronchoscopy, and that in some areas the remaining tumor cells were invading blood and lymph vessels. In his series of cases of adenoma, metastases have been found in mediastinal lymph nodes, in the parietal pleura and in many distant organs, particularly the adrenals and kidneys. Hence these tumors cannot be considered to be benign, and as their histologic structure is not that of an adenoma, the term benign adenoma is a most unfortunate one.

Dr Graham then projected a series of slides to show that material closely resembling fetal mesenchyme and fetal bronchi is sometimes found in these tumors. In fact there is a startling histologic resemblance between fetal lung tissue and biopsy specimens of these adenomas. In addition, bone and cartilage are seen in these tumors. Turning to the embryologic development of the lung, he showed that in the course of normal development there are excessive numbers of bronchial anlagen, many of which normally atrophy. He then postulated that these tumors arise from bronchial anlagen which would normally atrophy but for some reason fail to do so, and suggested the term "embryoma" as a more fitting name. Tumors arising from these anlagen would be expected to contain more than one type of tissue, connective tissue, bone and cartilage, as well as epithelial cells are found in these tumors. In Dr Graham's opinion the rare chondromas, fibromas, fibrosarcomas and lipomas have the same origin, and represent varying lines of differentiation. He suggested that in addition the round cell and oat-cell carcinomas and the adenocarcinomas have a similar origin from bronchial anlagen which have failed to atrophy.

In support of this theory, he showed that the lungs containing adenomas often have certain developmental abnormalities, such as, small accessory bronchi (in one case the lung contained ten or twelve of such bronchi), accessory lobulation, and abnormal development of fissures.

These tumors, and bronchiogenic tumors in general, are peculiar in that they often occur in young individuals. Many of the patients have a very long history of pulmonary symptoms, sometimes as long as eighteen years.

In summary, Dr Graham pointed out that the term adenoma was a very poor one, that these tumors should be regarded as potentially malignant, and that while bronchoscopic removal may be occasionally complete, more often a portion of the tumor is left behind.

The discussion was opened by Dr Edward D Churchill, who agreed that the term, adenoma, was a poor one. He stated that he was attracted to the hypothesis that these tumors arise from embryologic defects and agreed that these tumors should be regarded as dangerous lesions. Dr Richard H Overholt illustrated by figures from his clinic that the clinical diagnosis of carcinoma of the lung is now being made in a high percentage of cases, and that the mortality rate following pneumonectomy has now reached a surprisingly low figure, only 1 death having resulted from 11 pneumonectomies done in 1936 and 1937.

Following this a number of questions were asked of Dr Graham, who, in closing, answered as follows: (1) in the vast majority of cases fluid in the pleural cavity in cases of pulmonary carcinoma indicates pleural metastases and is a contraindication to operation, (2) it is possible to find malignant cells in pleural fluid in an appreciable percentage of cases, (3) in a case presented by Dr Henry L. Cabitt, in which an "adenoma" had been removed bronchoscopically and which now shows no evidence of tumor, he advised against an immediate pneumonectomy and favored waiting with close observation, (4) true papillomas of the bronchus do occur, but they are exceedingly rare, (5) there is no evidence that tuberculosis and bronchiectasis have any etiologic relation to pulmonary carcinoma, (6) in commenting upon a question concerning an apparent discrepancy between the results in Jackson's series of cases and his own conception of the nature of adenomas, he emphasized that he did not deny that in some cases bronchoscopic removal effects a cure, but that he did feel such an outcome is rare. He also pointed out that these tumors have the peculiar ability to form scar tissue at the point of biopsy, and that this may delude the bronchoscopist at subsequent examinations into believing no tumor is left behind.

NEW ENGLAND HEART ASSOCIATION

The regular monthly meeting of the New England Heart Association was held at the New England Deaconess Hospital on February 28. The following program was presented:

PROGNOSIS OF ADULT WOMEN WITH MITRAL STENOSIS Burton E Hamilton, M.D.

A group of 100 women of childbearing age, averaging twenty-nine years, with chronic rheumatic heart disease, were re-examined after an average interval of ten years. There were only 6 cases of rheumatic fever in 900 patient years. There was little evidence of a tendency for the rheumatic disease to progress, and less evidence that it tended to improve. Twenty-nine died. Seventy-four were in a favorable group when first seen, 20 per cent died. Of 26 in an unfavorable group, 54 per cent died. The mortality rate in the whole group and in all subdivisions were definitely better than that reported by Grant from a follow up of British soldiers with chronic heart disease. Among women who had uncomplicated mitral stenosis where a diastolic murmur of the aortic type appeared later, more often than not this murmur persisted. There was, however, definite evi-

Neither case developed edema or any signs of cardiac failure. In young cases of severe diabetic coma with anuria, therefore, there is little evidence that diabetic acidosis exerts any seriously harmful effect upon the heart.

SURGICAL TREATMENT OF HYPERTENSION Elmer C. Bartels, M.D.

Some benefits for patients with severe types of hypertension have been reported in recent years following the surgical interruption of the sympathetic fibers to the greater splanchnic region. Prior to 1937, operation was offered to a group of hypertensive patients who were usually more than fifty years of age and in whom evidences of great vascular change had taken place. It was evident that this group of 22 patients obtained subjective relief from the operation, although the blood pressure did not fall. In practically every instance in which headache was an outstanding symptom it was surprisingly relieved. Since the drop in blood pressure is the object of the operation care has been used in selecting patients who are more likely to obtain a definite beneficial result. Certain criteria have been laid down in selecting patients for the operation. The patient must be under forty years of age, evidence of advanced vascular injury to visceral organs, revealed by tests of renal and cardiac function, must not be present, and the blood pressure must approach a normal level when the patient is under induced rest or intravenous Pentothal-Sodium anesthesia. These requirements, of course, make the group of patients who are suitable for this operation small, and they make early diagnosis imperative. Early hypertension is usually asymptomatic, or evidence of nervous tension and occasional occipital headaches only are present. Many of the patients with hypertension who are suitable for this surgical procedure will therefore be found only after a routine general examination.

During 1937, 8 patients meeting the above requirements were subjected to operation. In all these cases the operation was that devised by Adson, in which the greater and lesser splanchnic nerves are divided subdiaphragmatically and resected with the lateral portion of the celiac ganglia with removal of the first and second lumbar ganglia and their rami. This approach permits bilateral exploration of the suprarenal glands.

A summary of the results in this group of patients from three months to one year after operation, gave the following results. One patient died of pulmonary embolus twenty days postoperatively. One patient with a very severe hypertension, having a diastolic pressure around 140 mm., has had a normal blood pressure for one year. Three patients have had a definite drop in the blood pressure which has been maintained. The blood pressure, however, did not reach a normal level. Three patients of the group, although having a normal postoperative pressure, gradually developed a blood pressure almost equal to the preoperative level.

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society was held in the Beth Israel Hospital on March 1. Dr. Kermit C. Rosen opened the meeting and introduced the speaker of the evening, Dr. Edward D. Churchill, who talked on "Present Day Surgery of the Chest."

Dr. Churchill began by discussing the development of thoracic surgery. The members of the strictly anatomical school of surgeons, and at a later date, of the pathological school were unable to treat thoracic conditions successfully because they did not fully understand the physio-

logic and biochemical features. These last two basic sciences have been especially important in the rapid advance of chest surgery that has been made in the past ten or fifteen years. The understanding of homeostasis, fluid balance, pressure relations, and so forth, are all important parts of a thoracic surgeon's training.

The treatment of tuberculosis by surgery gave a great impetus to all thoracic surgery, as have the improvements in x-ray, bronchoscopy, the injection of opaque substances and pneumothorax. The American Association of Thoracic Surgeons by its broad-minded, open-door policy through which it has allowed many doctors not primarily thoracic surgeons to become members, has greatly forwarded the advance of knowledge in this field. The influenza epidemic in 1918 left many cases of empyema which needed surgical treatment, and in this way forwarded thoracic surgery, but because of the deforming operations then in vogue, greatly harmed this branch of medicine by putting it in disfavor in the minds of many doctors.

Operations on the chest need be deforming only when the disease leaves a huge suppurating process within the thorax. Lung abscesses were discussed particularly in relation to extirpation of a part or all of one lung. Dr. Churchill pointed out that many cases eventually need surgery. For the surgical treatment of these cases he prefers two stages. By the first he creates adhesions and then opens the cavity and drains it in the second stage. These cavities may slowly close themselves, but some will not. Of those that remain open, some may be closed by inserting a muscle flap into the cavity, but others are too large for this procedure and it is in these cases that Dr. Churchill advocates removal of one lobe or occasionally of the entire lung. There may, of course, be more than one cavity and at times multiple abscesses may simulate chronic cystic disease of the lung. A chronic abscess is a distinct hazard to the patient, and there is also danger of complete destruction, hemorrhage, and so forth. In a few cases, primary extirpation is done before prolonged medical treatment is tried. This is especially true in abscesses involving multiple lobes of the lung, as they respond so poorly to drainage. These cases, of course, heal much more rapidly, and the end result is much more satisfactory and less deforming. The patients may have a stormy convalescence, and there is still a high postoperative mortality.

Dr. Churchill also described bronchiectasis and its surgical treatment. He pointed out the manifold etiology of this condition and spoke of the lesions of the end stages. Bronchiectasis is not a clinical entity. Lipiodol injection is essential in its diagnosis and Dr. Churchill showed lantern slides demonstrating the frequent involvement of the left lower and right middle lobes in the same patient. This probably occurs because of the posture of the patient during coughing. The lingula of the left upper lobe is diseased in about 35 per cent of the cases. At times the disease is entirely confined to the middle lobe of the right lung, and rarely to the upper lobe alone. Congenital malformation giving a honeycombed lung was mentioned, as was also the type of bronchiectasis with obstruction of the bronchus and collapse.

Extirpation of the entire lung is at times necessary in the treatment of primary pulmonary carcinoma. The bronchus must be extirpated as high as possible in order to include the large nodes which are around the hilum. The nodes in this area are frequent sites of metastases, and at times, metastases are found in these nodes in the opposite lung. Bronchial obstruction is common in carcinomatous involvement. It is necessary to make an early

sound was so loud that it was heard for a considerable distance from the body. Not only the patient, but other people, could hear it, the latter even before the patient entered the room. She described it as resembling the splashing of water in a mill.

The cause of the noise was discovered more or less by accident. She had moderately severe anemia which had not responded to treatment. X-ray examination of the gastrointestinal tract was made in order to see if there was any lesion responsible for loss of blood. It was found that she had a diaphragmatic hernia, a large part of the stomach was lying in the chest. The sound was produced through the action of the beating heart on the contents of the intrathoracic stomach.

THE BLOOD SUGAR AND CIRCULATORY FUNCTION IN DIABETES Howard F Root, M.D.

The regulation of the concentration of sugar in the blood involves many factors, even if we omit, for the moment, consideration of those factors such as changes in blood and lymph volumes which would influence the total amount of glucose in the body. The blood sugar concentration represents the resultant of oxidation storage and excretion on the one hand and formation and absorption on the other. The relative constancy of the concentration of blood sugar in the normal animal, a manifestation of homeostasis in the words of Professor Cannon, is extraordinary since the production, storage, and utilization of sugar are effected by many hormonal and nervous factors. It must be remembered that in diabetes, where the insulin supply and its effectiveness are of chief importance, all the other factors which influence the blood sugar are still operating, and often in pancreatic diabetes there may be secondary disturbances in other endocrine glands and in other tissues which will affect carbohydrate metabolism. The concentration of the blood sugar then is to be regarded as an index for metabolic changes in the tissues. No student of diabetes regards the exact amount of sugar in the blood as itself of great significance, but there is no doubt that the variations in blood sugar are of tremendous importance because of the wide variety of changes to which the blood sugar may give the clue.

HYPOLYCEMIA DUE TO INSULIN Howard F Root, M.D.

The danger of hypoglycemia produced by doses of insulin has been greatly stressed. If one attempts to study the electrocardiograms of young diabetics, particularly children, before and after hypoglycemia produced by insulin, certain slight changes do appear in the electrocardiograms such as slight alterations in the height of the T waves, slight variations in the lengths of the PR interval, changes in the height of the R wave and occasional extrasystoles. In this series, the attempt was made to produce only slight degrees of hypoglycemia in contrast to the studies made in Germany in which schizophrenics were observed who were undergoing treatment with profound hypoglycemia by means of insulin. In the latter cases the authors reported occasional changes in the T waves, the rare onset of auricular fibrillation, and variation in the length of the PR interval, but their conclusions were the same as those with our young cases: (1) the changes do not bear a quantitative relation to the degree or the duration of hypoglycemia or to the amount of insulin used and (2) the changes are temporary and inconsequential.

When hypoglycemia is so produced by insulin striking differences in the clinical symptoms, particularly those

referable to the cardiovascular system, appear from patient to patient. For example, the pulse rate may be lowered. In one instance, a young man who came into the Deaconess Hospital in profound hypoglycemia, the pulse rate was 62. This pulse rate remained constant even when he was struggling violently and was being held by three men. The first intravenous injection of glucose solution produced no effect. When the second one was finally accomplished, he suddenly became conscious and immediately the pulse rate increased to 85. On the other hand, in many instances the pulse rate rises materially with the blood pressure. One may interpret these changes as due to variations in the amount of adrenaline called forth by the hypoglycemia. Why there are such variations from individual to individual is still a mystery. Certainly in the cases where the pulse rate is slowed it is reasonable to assume that the preponderant effect of the hypoglycemic state has been exerted upon the central nervous system and that the slowing of the heart rate is a vagus effect.

In one young woman, a school teacher, twenty six years of age, who accidentally received an excessive dose of insulin and died after twenty two hours of hypoglycemia, no pathologic changes at autopsy were observed.

In older patients with coronary disease the danger of hypoglycemia would seem to depend upon adrenergic response with increase in blood pressure and the increase in the work of the heart which, occurring suddenly, might conceivably be fatal. On the other hand, it must not be taken as a reason for omitting the use of insulin in older diabetics with coronary disease. If one tabulates patients who have died of coronary disease according to the length of insulin treatment it is clear that the longer such patients are treated with insulin, the longer they live.

EXTREME HYPOLYCEMIA AND DIABETIC COMA. Howard F Root, M.D.

It has often been thought that the heart suffered a severe toxic injury during acidosis, although little evidence of such fact has really been brought forth, aside from occasional slight changes in electrocardiograms. In deed, Hamilton and Faulkner concluded that such changes as occurred were due to changes in acid-base relations and were not of serious import. The following 2 cases are reported as illustrating a type of physiological test of cardiac function during severe coma. Each of these patients received more than 10,000 cc. of liquid given intravenously and subcutaneously during a period of comparatively few hours for the treatment of diabetic coma with anuria.

Case 1 A woman, aged 31 years, was admitted with a blood sugar of 1194 mg and a carbon-dioxide-combining power of 3 vol per cent. She was first given salt solution containing glucose. She became anuric and during the next 2 hours when no urine could be obtained the blood pressure steadily fell until she was pulseless. A cannula was then tied into the vein and the intravenous salt solution continued until she had received 8000 cc. intravenously. The blood pressure had risen and anuria was at an end after a period of 12 hours.

Case 2 This woman, aged 25 years, similarly received glucose solution and salt solution, and as a result, the blood sugar rose from 700 to 1000 mg and she became pulseless and anuric. Similar treatment brought back secretion of urine and a rising blood pressure, after a period of 12 hours.

BOSTON CITY HOSPITAL

A symposium on pulmonary disease will be held on Saturday, April 23, at 10 15 a. m., in the Dowling Amphitheater. The papers to be presented are as follows

Pneumonia. Dr Maxwell Finland.
Pulmonary Tuberculosis. Dr Theodore L. Badger
Clinical Aspects of Pulmonary Disease. Dr John A. Foley
Locating Empyema. Dr Francis W. Palfrey
Pulmonary Abscess. Dr Louis M. Freedman
Pulmonary Surgery. Dr John W. Strieder
Discussion. Dr Horace Binney

ROBERT M. GREEN, M.D., *Chairman*
Committee on Hospital Clinics

BOSTON SOCIETY OF PSYCHIATRY
AND NEUROLOGY

The next meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library, 8 Fenway, on Thursday evening, April 21, at 8 15

PROGRAM

Relief of Unilateral Paralysis Agitans by Section of the Pyramidal Tract. (Moving picture demonstration and presentation of case.) Dr Tracy J. Putnam

Electromyographic Studies in Spastic Conditions and in Paralysis Agitans. Dr Paul Hoefler and Dr Tracy J. Putnam

Results in the Treatment of Chronic Alcoholism by Benzadrine. A preliminary report. Dr Wilfred Bloomberg

The Incidence and Age of Cessation of Enuresis in One Thousand Neuropsychiatric Patients. Dr Joseph J. Michaels and Sylvia E. Goodman

H. HOUSTON MERRITT, M.D., *Secretary*

JOINT MEETING OF THE SUFFOLK DISTRICT
MEDICAL SOCIETY AND THE BOSTON
SURGICAL SOCIETY

There will be a joint meeting of the Suffolk District Medical Society and the Boston Surgical Society at the Boston Medical Library, 8 Fenway, on Wednesday evening, April 20, at 8 15

Dr Augustus Thorndike, Jr., will speak on Trauma Incident to Sport and Recreation. Diagnosis and treatment. The paper will be discussed by Drs. Bernard A. Godvin, Henry H. Faxon and Charles C. Lund

JOHN P. MONKS, M.D., *Secretary*
Suffolk District Medical Society

GRANTLEY W. TAYLOR, M.D., *Secretary*
Boston Surgical Society

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Thursday, April 21, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), at 8 15 p. m. *Note change from usual day of meeting*

PROGRAM

Adrenalin Sensitivity in Hyperthyroidism. Dr Emil Goetsch, professor of surgery, Long Island College of Medicine.

The Value of Antitoxin in Scarlet Fever. Dr Francis G. Blake, Sterling Professor of Medicine, Yale University School of Medicine.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING
MONDAY, APRIL 18

MONDAY APRIL 18

*11:30 a. m. Carney Hospital. Monthly staff meeting and luncheon

WEDNESDAY APRIL 20

9 10 a. m. Boston Dispensary. Hospital case presentation. Dr S. J. Thannhauser

*12 m. Clinopathological conference. Children's Hospital amphitheater

5 15 p. m. Joint meeting of the Suffolk District Medical Society and the Boston Surgical Society. Boston Medical Library 8 Fenway

THURSDAY APRIL 21

8 30-9:30 a. m. Exchange visit surgical and orthopedic staffs of the Peter Bent Brigham and Children's hospitals, held this week at the Peter Bent Brigham Hospital. Rounds conducted by Emil Goetsch, professor of surgery, Long Island College of Medicine, surgeon-in-chief, Long Island College Hospital, Brooklyn, surgeon-in-chief pro tempore, Peter Bent Brigham Hospital

9-10 a. m. Boston Dispensary. Follow up of interesting diagnostic problems: presentation of former diagnostic hospital patients. Dr H. G. Brugh.

8 15 p. m. Boston Society of Psychiatry and Neurology. Boston Medical Library 8 Fenway

*8 15 p. m. Harvard Medical Society. Peter Bent Brigham Hospital amphitheater

FRIDAY APRIL 22

*9-10 a. m. Boston Dispensary. Surgery of Peripheral Vascular System. Dr James C. White.

*10 a. m. 12:30 p. m. Tumor clinic. Boston Dispensary

4 p. m. Massachusetts Society for Social Hygiene. State suite salon, Copley Plaza Hotel, Boston

SATURDAY APRIL 23

9 10 a. m. Boston Dispensary. Hospital case presentation. Dr Thannhauser

10 a. m. 12 m. Staff rounds at the Peter Bent Brigham Hospital. Conducted by Dr Henry A. Christian

10-15 a. m. Symposium on pulmonary disease. Boston City Hospital, Dowling amphitheater

SUNDAY APRIL 24

4 p. m. Illustrated public health lecture. Faulkner Hospital auditorium. Syphilis: its cause, prevalence and eradication. Dr Franklin Balch, Jr.

Open to the medical profession

diagnosis in these cases in order to obtain the best results, and the size of the tumor is not related directly to the prognosis. Dr Churchill pointed out that benign tumors may kill by infection or bronchial obstruction. Charts were shown to demonstrate the mortality in all cases done at the Massachusetts General Hospital. A total of 117 lobectomies were performed with a mortality of 68 per cent. The mortality of total pneumonectomies was between 35 and 50 per cent. The technic of this method was discussed. One hundred cases of primary carcinoma of the lung were classified, and it was found that 51 per cent of these were epidermoid carcinoma of the squamous-cell type, 21 per cent adenocarcinoma, and 28 per cent oat-cell or undifferentiated types.

NOTICES

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Boston Medical Library on Monday, April 25, at 8 15 p m.

PROGRAM

Heart Disease in Pregnancy at the Worcester City Hospital. Dr F B Carr, of Worcester.

Electrocardiographic Changes in Vitamin B Deficiency. Drs C C Dustin, H L C Weyler and C P Roberts, of Providence, Rhode Island.

Gall Bladder Disease and Coronary Sclerosis. Dr E H Drake, of Portland, Maine.

A Case of Hemophilia with Hemopericardium as a Result of Trauma. Dr C C Dustin, of Providence, Rhode Island.

Clinical Observations on the Use of Quinidine. Dr James Z Naurison, of Springfield.

Auricular Flutter. Report of an unusual case with some remarks about the history of our knowledge of this disorder. Dr Frank T Fulton, of Providence, Rhode Island.

Interested physicians and medical students are invited to attend.

JAMES M FIVULKNER, M.D., *Secretary*

CARNEY HOSPITAL

The monthly staff meeting and luncheon of the Carney Hospital will be held at the Carney Hospital on Monday, April 18, at 11 30 a m.

PROGRAM

Case Report. Vesico-vaginal fistula treated by colpocleisis. Dr L E Phaneuf.

Occiput Posterior Positions and Their Management. Dr B F Macchia.

Discussion by Drs J J Meehan, F Fortun and E L Kickham.

Physicians and medical students are invited to attend.

R J HEFFERNAN, M.D., *Secretary*

MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

The annual meeting of the Massachusetts Society for Social Hygiene will be held in the State Suite Salon of the Copley Plaza Hotel, Boston, on Friday, April 22, at 4 00 p m.

Dr George G Smith, president, will review the work of the past year and Mr Lester W Dearborn will report on the progress of the counseling service of the society.

The guest speaker, the Honorable Kenneth D Johnson, former special justice of the district court of East Norfolk, will speak on 'Marriage—Can It Be Adjusted?'

The meeting will be open to the public without charge and a special invitation is extended to all physicians, medical students, nurses and social workers.

MRS S W MILLER, *Secretary*

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Ring Sanatorium and Hospital, Arlington Heights, on Wednesday evening, April 20, at 8 00.

Dr William Benham Snow, associate in medicine, College of Physicians and Surgeons, Columbia University, and director of physical therapy, Columbia Presbyterian Medical Center, will speak on "The Rationality, Practicability and Limitations of Induced Fever as a Therapeutic Agent." Discussion by Dr Michel Pijoan and Dr Hosea W McAdoo.

The Council will meet at 6 o'clock, and dinner will be served in the main dining room of the Sanatorium at 6 30 p m.

All members of the medical profession are cordially invited to attend.

WILLIAM D McFEE, M.D., *Secretary*

LAWRENCE CANCER CLINIC

A special Lawrence Cancer Clinic, to be held at the Lawrence General Hospital, 1 Garden Street, Lawrence, on Tuesday, April 26, at 10 00 a m, will be a demonstration and teaching clinic for physicians, with Dr Channing C Simmons present as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

A series of cured cancer cases will also be presented. This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society.

ROY V BAKETEL, M.D.,
CHARLES J BURGESS, M.D.,
JOHN J McARDLE, M.D.,
HARRY H NEVERS, M.D.,
THOMAS V UNLAC, M.D.,
J FORREST BURNHAM, M.D., *Chairman*

NEW ENGLAND PATHOLOGICAL SOCIETY

There will be a meeting of the New England Pathological Society at the Worcester City Hospital, on Thursday, April 21, at 8 00 p m.

PROGRAM

Monocytic Leukemia with a Report of Two Cases. Dr Louise M. Norton.

A Study of Lymphoid Nodules in Bone Marrow. Dr Robert Williams.

A Study of Central Autolysis of the Adrenal Glands. Dr William Freeman.

Members of the medical profession are cordially invited to attend.

J B HAZARD, M.D., *Secretary*

the greater part of her time in the British Museum Library. The book under review is the result of her efforts.

The subject is covered adequately from ancient times through the end of the eighteenth century. The author seems not to have missed any important woman physician in the history of medicine and many historians will be grateful to her for bringing to light the names of many previously unknown. Naturally, her best efforts are directed toward Trotula, the great woman physician of Salerno. There seems to be no one quite so outstanding as this woman physician and teacher in the whole history of female medicine. Long chapters follow on the medical women of the twelfth through the eighteenth centuries, each century receiving a careful analysis of thirty to forty pages. In addition, the book is profusely illustrated but, unfortunately, neither the plates nor the figures are numbered and there is no reference to them in the text. The references to the literature, given as footnotes to each page, are, in general, correct, but their form is irregular and the use of "op cit." is greatly to be deplored. The book is fairly well printed and has an adequate index. In general, it speaks for the scholarly work of the author and must be considered the outstanding volume on this subject.

The Conquest of Cholera America's greatest scourge
J S Chambers. 366 pp New York The Macmillan Company, 1938 \$4.75

This book has held the reviewer's attention from cover to cover. The author presents an absorbing story of the halting progress of scientific truth in a dramatic field of medical history.

The several epidemics of cholera which have swept over our country in the past are portrayed in a vivid and pleasing style. Apt quotations from contemporary sources contribute high lights as well as dark shadows to the picture.

The text is scholarly, well documented and reveals study of the subject along very broad lines. This book can be read with profit as well as pleasure not only by physicians and medical students but also by laymen.

Claude Bernard Physiologist J M D Olmsted. 272 pp
New York and London Harper & Brothers, Publishers, 1938 \$4.00

Claude Bernard may be rightfully designated as the father of modern physiology. His life is therefore of great interest to all physicians. Born of relatively obscure parents, he started his career by writing a play while he was working in a pharmacy to earn his living. Taking the play to Paris, he was advised not to adopt literature, but to study medicine. This he promptly did, although he never entered into practice. He soon saw the great opportunity open to him, in the middle of the nineteenth century, for physiological experimentation, and having a sort of intuitive power for investigation with assurance and precision of action, he shortly discovered the glycogenic function of the liver and the important part that the brain plays in carbohydrate metabolism. Most of his early work had to do with digestion, particularly the function of the pancreas. Later he turned to the action of nerves, muscle physiology and the effects of poisons.

A contemporary of Pasteur he was considered by many during his life as the greater man. Pasteur, however, has grown with the years whereas Bernard's influence except in the strict field of physiology, has not been widely appreciated. Professor Olmsted's book will do much to overcome this point of view. The first half of the book deals with the biography of the man while in the

latter half his discoveries are taken up in detail. Well illustrated and carefully documented, this book is a distinct addition to medical biography and should be widely read.

Collected Papers on Tuberculosis Sir Robert W Philip
460 pp New York Oxford University Press, London
Humphrey Milford, 1937 \$7.50

Sir Robert Philip is an outstanding authority on tuberculosis. He graduated from medical school in 1882, the year when Koch announced the discovery of the tubercle bacillus and ever since has been a leader in the British campaign for the eradication of the disease. The present volume presents twenty-four papers and addresses covering the period from 1898 to 1934. Here are summarized the writer's contributions to science and society.

Most of the papers have to do with the organization of the agencies which have been developed to fight tuberculous infection. The author has worked for the establishment of the dispensaries, sanatoriums, hospitals for advanced cases, tuberculosis colonies, and so on. He was also a prime mover in the effort to make compulsory the reporting of cases of pulmonary tuberculosis. Of particular interest is the last paper entitled, "Musings in the Garden Fifty years association with the tubercle bacillus."

On the scientific side, the author has stressed the open air treatment of the disease, and still believes that tuberculin plays an important part in the treatment as well as in diagnosis of tuberculosis. He also makes a great point of the importance of tuberculous infection in the lymphatic system, and thinks that tubercle bacilli are usually carried to the lungs not by direct inhalation but through the lymphatics after having penetrated the mucous membrane of the pharynx.

These papers are of historical importance, and make interesting reading.

Handbook on Nasal Accessory Sinuses Frank L. Alley
121 pp Kingsport, Tennessee Kingsport Press, Inc., 1937 \$2.00

This small handbook of 120 pages, two thirds of which is devoted to operative procedures on the nasal sinuses, is essentially a collection of lectures. The early chapters deal briefly with anatomy, symptomatology, pathology and diagnosis.

It is evident that the subject would make an interesting presentation to students if supplemented by charts and anatomical and clinical demonstrations. The almost total lack of illustrations, either anatomical or clinical, so reduces the effectiveness of the text as to leave one in doubt for whom the book is intended. Any specialist sufficiently versed in operative technic so as to need no textual illustrations would find little that he does not already know. For the general practitioner for whom sinus surgery is utterly outside his field, the rather brief presentation of symptomatology and diagnosis would not seem adequate, even if perused for more than "a few hours." The masquerading of empyema as "emphysema" and "emphvema" leaves something to be desired in proof reading.

The Management of the Pneumonias For physicians and medical students Oxford Medical Publications, Jesse G M Bullowa. 508 pp New York Oxford University Press, 1937 \$8.50

This is a timely book. It treats very well the whole problem of the management of the pneumonias. However, it is of especial interest to physicians who are dealing with

BOOK REVIEWS

Mentality and Homosexuality Samuel Kahn. 249 pp. Boston Meador Publishing Company, 1937 \$3.00

In this volume, Dr Kahn gives a description of homosexuality to determine the peculiarities of the homosexual and the causes, diagnosis, prognosis and therapy of this particular inversion. He has accumulated a mass of valuable material on male and female homosexuals, but this material is limited more to its descriptive than to its dynamic aspects. The fundamental psychoanalytic theories are reviewed rather meagerly, for instance, there is no reference to Freud's important contribution on the psychogenesis of female homosexuality.

The author's studies are based on material from Blackwell's Island, at the New York County Penitentiary for male prisoners and at the Women's Workhouse for women prisoners, about five hundred cases in all. Seventy-five of these are described in detail with their clinical histories and psychometric tests. It is pointed out that latent homosexuality is particularly apt to become active when groups of men with restricted liberties congregate together, but it is the sexual invert or pervert who lives in the community that is most apt to commit sexual crimes. The reviewer would emphasize that inverts or perverts are not responsible for their abnormal sexual acts, they are not 'degenerates' according to the popular viewpoint and should not be punished, or threatened with punishment, for their sexual abnormalities, as such procedures do not cure a homosexual. What the homosexual needs is not criticism but sympathetic understanding, and yet, at the same time, homosexuality should not be idealized, as it has been by some writers, because certain great men and women have been homosexuals.

According to the author, the only radical therapy for homosexuality is psychoanalysis but, even with this therapy, the prognosis should be guarded. He emphasizes that the average intelligence of the homosexual in penal institutions is somewhat higher than that of the non-homosexual inmates. However, the reviewer must point out that intelligence tests and intelligence quotients throw no light upon the total personality of the homosexual.

The volume deals with the methods of examination, which are important since the patient tries to conceal his homosexuality rather than to speak freely of it as he does in private psychiatric work, and with the various psychological, physical and sociological factors which appear to be most characteristic in the development of homosexual trends, and, even if it gives a limited insight into the psychogenesis of homosexuality, yet it provides a convenient working manual for those who have to deal with these particular problems in penal institutions.

A History of Women in Medicine From the earliest times to the beginning of the nineteenth century Kate Campbell Hurd Mead. 569 pp Haddam The Haddam Press, 1938 \$6.00

This book, like so much that has appeared in America in the last thirty years, is the direct result of the influence of William Osler. In 1890 the author was inspired by the programs of the Historical Club of the Johns Hopkins Hospital, and was much enlightened by the wit and erudition of Osler, Welch and Kelly. At that time she began a study of woman's place in the development of medicine. This was carried out intermittently from 1890 to 1925 in association with her active private practice. On her retirement, however, she began devoting long hours to actual historical research and for two years spent

THE ETIOLOGY OF LUNG ABSCESS

A Clinical Analysis of 447 Cases Occurring at the Boston City Hospital
from 1926 to 1935, Inclusive

LOUIS M. FREEDMAN, M.D.*

BOSTON

THE etiology of lung abscess has become a matter of special concern to otolaryngologists, particularly because of the fact that tonsillectomy has been found to be the background of a large percentage of these cases in most of the large clinics. The literature is replete with such reports showing percentages varying from 10 to 40 per cent or more. Lord¹ in a series of 227 cases found that in 22 per cent the abscess developed as a sequel of tonsillectomy. Hedblom² in a total of 692 lung abscesses found 31 per cent to follow tonsillectomy. Schlueter and Weidlein,³ in a series of 1908 cases attributed 15 per cent to tonsillectomy. Pinchin and Morlock⁴ in England, show that 12 per cent of their 25 cases of lung abscess followed tonsillectomy. It is notable that, although the percentages vary considerably, in the series containing the largest number of abscesses the incidence of those following tonsillectomy is relatively low. Similarly Moore,⁵ in a questionnaire to otolaryngologists all over this country, gathered reports of 450,000 tonsillectomies, 202 of which were followed by lung abscess—a ratio of 1:2200. Crowe and Scarff,⁶ of the Mayo Clinic, recorded 3500 tonsillectomies, not one of which was followed by lung abscess. This is in agreement with Moore's finding that the larger the number of tonsillectomies performed, the smaller the percentage of lung abscess as a complication. Added to this fact is the outstanding one that most otolaryngologists encounter lung abscesses only occasionally. Apparently no attempt has been made to determine the incidence of lung abscess following operations on the upper respiratory tract, or to compare such a figure with that following other operative procedures or medical conditions such as pneumonia. Maxwell⁷ in a study of 315 autopsies following deaths from lung abscess at St. Bartholomew's and

the Royal Chest Hospital, in London, analyzed all the causes, and found a small number of lung abscesses following operations on the upper respiratory tract in comparison with all other causes (Table 1). Although this series represents only cases which failed to survive, the figures are of interest because they are very much the same as those found in the foreign literature covering the incidence of all types of lung abscess regardless of outcome.

This table shows how much more important a role pneumonia and abdominal operative procedures play in these cases than do operative conditions involving the upper respiratory tract. This being so, it seemed to me that a study of all lung abscesses, of both medical and surgical origin, occurring in a large clinic such as that of the Boston City Hospital over a ten-year period, would be of value in classifying this complication, and might produce some interesting and important data. This clinic has served the purpose especially well because it cares for a large clientele of indigent individuals who have little means for paying ward rates or professional fees. As a result, not only do patients with serious postoperative complications return to the hospital, but others operated on elsewhere come there for the treatment of long-drawn-out complications, which would otherwise be expensive.

The period from 1926 to 1935, inclusive, was chosen for this investigation. All lung-abscess cases were abstracted, studied and classified. Similarly, all the operative procedures carried out during this period were totaled, so that the ratio of operations to lung abscess could be determined.

A total of 447 cases in which the diagnosis of lung abscess was at any time made were abstracted, and all proved lung abscesses were selected for comparative study. X-ray pictures were examined, and histories and autopsy reports were studied

Read before a meeting of the New England Otolaryngological Society, Boston, November 16, 1937.

Surgeon-in-chief, Boston City Hospital and Beth Israel Hospital, Boston.

comparatively large numbers of pneumonia patients, because it takes up the discussion of the different types of pneumococci, their relative frequency in the pneumonias of adults and children, the varying clinical pictures produced by each type, and the results of serum treatment in the types for which a serum is available. The conclusions are drawn, for the most part, from the study of over 600 cases observed at the Harlem Hospital during the period from July 1, 1928 to June 30, 1936.

Besides the directions for the routine use of serum, there is a detailed discussion of lung taps, their use, and dangers in obtaining pneumococci for typing, agglutination tests and their value in determining whether sufficient serum has been given, the use of serum in hypersensitive reactions, oxygen therapy and the relative merits of different types of apparatus, the treatment of pulmonary edema, and a short section on the use of rabbit serum and sulfilamide.

The notes with interest that "our Harlem Hospital experience is not sufficient to establish statistically the value of serum therapy for Pn II." It seems a little strange that the author should have to combine his figures with those from the Boston City Hospital to find a significant difference in the death rate of the serum treated cases.

The author is in error when, in discussing the differential diagnosis of lobar pneumonia and pulmonary tuberculosis, he says, "A low blood count with a relative lymphocytosis suggests tuberculosis." Such a blood is that of active pulmonary tuberculosis, and not that of active tuberculous infection.

Good progress is being made in the management of pneumonia and any statistics are certain to lose some of their usefulness, but this book is the only work available which covers all of today's needs. Anyone seeing more than a few pneumonia cases will need this book for his treatment of patients in the next few months.

Step in Sex Education Edith Hale Swift 207 pp New York The Macmillan Company, 1938

This book, indirectly the result of problems arising in the author's own family, undertakes to show in a specific way how sex education of children between two and twelve can be successfully carried out at home. With the character of the teachings no one could quarrel with the method of presentation—that of dramatized conversation between father, mother, son and daughter—besides the fact that in a way it adds force, a little. The most effective sex teaching comes general response to the child's questions, but one wonders if Dr. Swift does not presuppose a greater knowledge of physiology, venereal disease, and the like, on the part of the parents, than the majority of them are likely to possess, even in this age of population. The conscientious parent will ground his child as well as possible in anticipation of the inevitable, then he will find this book as good as any to aid in the effective conveyance of the facts.

Diseases of the Hip Surgery and conservative treatment Fred H. Albee, assisted by Robert L. Pres. 8 pp New York Paul B. Hoeber, Inc., 1937

This book of three hundred pages concerning the diseases and diseases of the hip joint. It is very well illustrated by x-ray photographs and especially by the showing surgical technic.

The largest portion of the book is devoted to fractures of the hip and congenital dislocations. In the first group of cases the author emphasizes his own method of bone graft from the tibia, both in fresh and old fractures, although he does describe other methods. This makes it not a textbook but one in which the author's own technic is described.

The portion dealing with congenital dislocations emphasizes the operative technic that he uses in the so-called shelf operations.

It is a book for the orthopedic surgeon rather than the general practitioner.

Love and Happiness Intimate problems of the modern woman I. M. Hotep 235 pp New York and London Alfred A. Knopf, 1938 \$2.00

Modern woman, invested with a freedom never before accorded to her sex, is faced with new and pressing problems, particularly those centering about sex. To state some of these problems and to give reasons for and against one or another of the available solutions is the author's object in writing this book. Unnamed though he prefers to remain it is obvious that he is a man of wide experience, of liberal and independent thought, broadly tolerant of the biologic urges, and even the frailties, of humankind. And he writes very well indeed. Being eminently modern he does not hesitate to call a spade a spade, but there is not a trace of pornography in his discourse. It is a book which should help many women to a better insight of their personal problems. The only ones who will be offended are those who still adhere to the regulations of sexual conduct solely by authority.

Introduction to Ophthalmology Peter C. Kronfeld. 331 pp Springfield, Illinois, and Baltimore Charles C. Thomas, 1938 \$3.50

This book is designed as a second reader for students in ophthalmology. It contains no exposition of methods for ophthalmic examination, and no details for diagnosis or treatment.

Diseases and abnormalities of the eye are discussed in terms of pathogenesis, correlating the recent advances in fundamental sciences with clinical ophthalmology.

The text contains 331 pages, with 32 illustrations and 5 plates, all in black and white, and an adequate index.

It is a work to be studied with interest and profit by anyone who has completed a beginner's course in ophthalmology.

Essentials of Prescription Writing Cary Eggleston. Sixth edition, revised. 155 pp Philadelphia and London W. B. Saunders Company, 1938 \$1.50

This admirable book now appears in the sixth edition revised in conformity with the eleventh edition of the *U.S. Pharmacopoeia* and the sixth edition of the *National Formulary*. It is compact in matter and form, indispensable to the medical student and may be of no little help to many physicians in writing properly composed and accurate prescriptions. The section on Latin grammar might well be learned by anyone, although this reviewer agrees with the author that prescriptions to be filled in this country should be written in English.

While the apothecary's system of measure is in wide use and sanctioned by tradition in many of the older hospitals, the reviewer is also inclined to agree with the author that the metric system should be used.

victims of alcoholism. Unclean mouths and bad teeth and gums were present in nearly every case. Some patients had chronic lung trouble, such as bronchitis, asthma or bronchiectasis. All these conditions represented fertile soil for active lung infection. Supervening upon this and acting as a precipitating cause, were influenza and pneumonia. With the acute reaction incident to these infections, atelectasis to a smaller or larger extent took place, and the sequence of events was pneumonitis, necrosis and abscess formation.

The bacteriological findings in all these cases were not uniform. Anaerobes, streptococci, staphylococci, pneumococci, fusiform bacilli and spirochetes were present in various combinations. Even though an occasional case materially improved when arsphenamine was used, by and large this drug did not seem to affect materially the course of the disease. The claim that is sometimes made that spirochetes and fusiform bacilli are the important factors in the production of these abscesses was therefore not substantiated by our analysis. It would seem that this is not the only type of infection that is operative. The importance of the general condition of the patient, the virulence of the organisms, and the mechanical factors involved in atelectasis, which was probably present in a large percentage of the cases, cannot be overestimated in the production of abscess.

One is struck by the large number of cases following pneumonia or pneumonic processes. In this ten-year period there were 15,177 cases of pneumonia in the Boston City Hospital, and 104 cases of lung abscess following pneumonia, a ratio of 1:146. This complication was recognized by many earlier writers, among them Laennec,⁸ Zenker⁹ and Tuffier.¹⁰ In fact, lung abscess was considered a fairly frequent sequel to pneumonia. But as increasing attention was focused on lung abscess as a postoperative complication, particularly following tonsillectomy, pneumonia and general respiratory infection received less and less serious consideration as causes. A contributory factor was the realization that the pneumococcus was frequently not the only organism present. With the advent and the great spread of modern surgery came a tremendous increase in postoperative complications, as a result of which pneumonic conditions per se receded as a cause of lung abscess. The present survey, however, again reveals that a very large proportion of lung abscesses are still due to acute and chronic pneumonic processes, and in all probability outnumber those occurring as postoperative complications.

POSTOPERATIVE LUNG ABSCESS

We now come to a consideration of the lung abscesses which followed operative procedures. There

were 76 such cases in this series. In addition, 13 patients who had had tonsillectomies performed elsewhere were brought to the Boston City Hospital for the care of the pulmonary complications. These cannot be included in our figures in showing the relation between operative cases and ensuing lung abscess. Such cases are not unusual, because tonsillectomy patients usually leave the hospital within a day or two after the operation, whereas in almost all other cases the hospital stay averages ten days, during which lung abscess is likely to occur. It has therefore happened that the tonsillectomy was performed at one hospital and the postoperative complication was cared for at another. Furthermore, many patients with acute postoperative atelectasis, infarction, or pneumonia following abdominal operations die before a lung abscess can supervene. These cases also cannot be included in our figures, but offer food for serious speculation.

Table 4 Postoperative Lung Abscesses (76 cases)

Gall bladder	9
Uterus and tubes	14
Total cases	76

Table 4 represents the distribution of our 76 cases of postoperative lung abscess. They were studied with the special purpose of finding, if possible, common factors as a background for the ensuing abscess. Most of these patients were in poor physical condition, the operations and anesthetics, except for the upper respiratory tract, were of long duration, and opportunities for complications were frequent.

The distribution of abscesses was greater for the right lung and lower lobes (Table 5), as was

found in the cases following pneumonia or infection of the nonoperative type. This distribution is important because it is most typical of abscesses of aspiratory origin. On the other hand, those who favor embolus as a cause point to the fact that in proved embolic cases also the abscess distribution favors the right lung and lower lobes.

The total numbers of the more common operations performed at the Boston City Hospital during the years 1926-1935, inclusive, are given in Table 6, together with the cases subsequently de-

The total of lung-abscess cases accepted for investigation was 276. These were then separated into those of postoperative origin and those with other causes, 196 cases were of medical origin, 76 occurred as a postoperative complication and 4 were a result of trauma.

Table 2 represents all lung abscesses occurring in patients who had not been operated on. The 57 cases of chronic cough included bronchitis, asthma and bronchiectasis, and a number of factors, such as arteriosclerosis, cardiac disease and alcoholism, were involved. In these no definite history of pneumonia or influenza as a background could be elicited. Undoubtedly a fair percentage could have been traced back to the common cold, influenza or some acute process, with intervening atelectasis. In studying these abstracts it became

evident that in the latter half of the decade there was a gradual realization on the part of physicians of the role that pulmonary atelectasis plays in stagnation of infected material in shut-off portions of the lung.

Of the 196 cases of medical origin, 189 were

figures it is evident that the right lung and the lower lobes were more commonly affected than the left lung and the upper lobes. Almost all the abscesses following an acute process, with the exception of those due to acute sepsis and those following accident, were solitary. The multiple abscesses were those of chronic background. It is quite possible that there were more cases of multiple abscess than were diagnosed as such. Some of the cases which came to autopsy were found to have multiple abscesses, although during life these abscesses were diagnosed as solitary. For that reason the solitary and multiple abscesses were consolidated in one table, although only 7 cases of this series were proved to have multiple abscesses.

LUNG ABSCESS OF MEDICAL ORIGIN

Examination of all cases of lung abscess following medical conditions disclosed certain definite common factors.

A great number of these patients were in poor general condition. Some had diabetes, arteriosclerosis or cardiac disease, and a number were

cently we saw a patient who was prepared for tonsillectomy, which was not performed because of infection present in the lower respiratory tract. This patient developed a lung abscess, which would have been laid at the door of the tonsillectomy. We are convinced that the major source of lung abscess following tonsillectomy is the preoperative condition of the respiratory tract.

As to the type of anesthesia, lung abscess occurs when local anesthesia is used, but quite infrequently. Most clinics record a minimal percentage. It is true that abolition of the throat and laryngeal reflexes allows for the easy entrance of blood and septic material from the throat and tonsils into the trachea, but it does not follow that this in itself is sufficient to cause a pulmonary complication. Myerson¹¹ examined bronchoscopically 100 cases in which tonsillectomy was done under light general anesthesia, and found blood present in 76, even with the cough reflex present. He found that foreign material was evacuated from the lungs in twelve minutes, even under general anesthesia, in the absence of the cough reflex. The laryngeal reflex does not ensure the presence of cough. Patients will cough only when there is increased irritability in the respiratory tract, under light anesthesia. Iglauer¹² found blood in the trachea in 40 per cent of his patients under general anesthesia, and in 38 per cent under local. It is the prolonged retention of aspirated blood and septic material from the throat that helps to produce abscess.

Although Le Play¹³ in 1905, Grossard and Kaufmann¹⁴ and others, began to recognize post-tonsillectomy lung abscess as a distinct entity, it was Richardson¹⁵ who in 1913 first called serious attention to this condition. At the outset he favored embolism, later he became entirely convinced that aspiration was the most important factor. In 1916 Manges¹⁶ reported 9 cases in a single year, he thought they were all aspiratory in origin and blamed the upright position. Yanlauer¹⁷ thought that the gaping veins in the tonsillar fossas easily became thrombosed and caused septic infarcts in the lungs. From then on there were many reports from all over the country, until Moore³ in 1922 called attention to the occurrence of only 202 cases in his series of 450,000 tonsillectomies, a ratio of 1:2200. In all the reports local anesthesia held a very minor place, and general anesthesia was the background in an overwhelming percentage. The fact that most of these abscesses are related to the bronchial tubes rather than to the periphery of the lung distinctly favors aspiration as a cause. Furthermore, the fact that these abscesses occur most frequently in the right lung and in the lower lobes likewise favors aspiration, even though those who favor

embolism point to a similar distribution in cases of proved emboli. Bronchial obstruction is so frequent an occurrence that it is difficult to believe that aspiration is not the most natural mechanism of this condition. The work of Coryllos and Birnbaum¹⁸ on pulmonary atelectasis and the convincing evidence of Harkavy¹⁹ are most potent arguments in favor of aspiration, and atelectasis with retained septic material, as the background.

On the other hand, the experimental work of Fetterolf and Fox,²⁰ Cutler and Hunt,²¹ Cutler and Schlueter²² and others strongly favors embolism. Much experimental work has been done, being designed to reproduce lung abscesses in animals by aspiration and by embolism. Both methods have eventually proved successful. Much doubt has been cast on such experimentation because it has been impossible to be sure that its results were equally applicable to man. The differences in the animal tissues including the pulmonary circulation, together with the normally horizontal position of the trachea in animals as contrasted with the vertical position in man, throw doubt on the validity of these experiments. Moreover, chronic lung abscess has not been produced in animals, because of the tendency of the experimental abscesses to spontaneous healing.

While there is no doubt that lung abscesses occur as a result of aspiration and also by embolism, clinically the preponderance of opinion favors the aspiratory mechanism as the cause in the greater number of cases.

FOREIGN BODIES IN THE BRONCHIAL TUBES

It is striking that in the many foreign-body cases that come to our clinic each year there are not more resultant lung abscesses. This is due to a number of causes. Primarily, physicians and the community at large are more awake than formerly to the possibilities of danger from foreign bodies in the air passages. Likewise, clinics are far better equipped to handle these cases, so that early removal of the foreign body is commoner. Metallic or hard non-opaque bodies do not tend to cause abscess, and in the absence of degenerative substances or infection most of these cases clear up on removal of the foreign body before there is any chance that obstructive infection will occur. It is the vegetable or animal matter tending to cause inflammatory reaction with infection that is most prone to cause abscess. These cases also, when seen early, are likely to recover with adequate drainage as soon as the foreign substance is removed. In our clinic we have had to deal with 188 cases with foreign bodies during this period, only 1 was productive of a lung abscess. In that case, delay in coming to the clinic for

veloping lung abscess. More lung abscesses followed operation for removal of tonsils and adenoids than for any other operative procedure, but because of the large number of operations—twice that of any one of the others—the ratio of incidence (1/1654) was the lowest of all.

*Seven year period 1929-1935 inclusive

Table 7 gives the total number of cases of lung abscess developing after operations on the upper respiratory tract and after abdominal operations.

POST-TONSILLECTOMY ABSCESS

Of the 26,473 tonsillectomies and adenoidectomies performed, 17,705 were on children and 8768 on adults. Two abscesses followed those performed on children, and 14 followed those on adults. General anesthesia was used for all the children. Eighty-five adults were operated on under local anesthesia, and the rest under general anesthesia, none of the former developed lung abscess. The ratio of lung abscess to operation in the 26,473 cases was 1/1654—1/8852 in children and 1/626 in adults. There was much variation from year to year in this ratio. In 1935 there were no lung ab-

scesses and 4241 tonsillectomies. The last three years of the decade produced 5 lung abscesses, or a ratio to tonsillectomies of 1/2309. In the last five years there has been a greater realization of the need for careful observation, and as a result of more conscientious attention to preoperative condition and to methods of procedure, complications have been less frequent. Presumably because otolaryngologists always pay more personal attention to their private cases than they do to those in the hospital, the incidence of lung abscesses in such cases is low.

In our study of post-tonsillectomy lung abscesses, we examined the factors concerned in their production in the light of our experience with the

methods used in this institution. We divided these into *extrinsic* and *intrinsic* factors. The former we considered those which did not depend upon the patient or did not concern his general condition. These were operative position,—upright or Rose,—the use of suction during operation, and preoperative medication. All other factors, classed as *intrinsic*, included the patient's preoperative condition, the kind of anesthesia employed, operative trauma and bleeding, and aftercare.

Among the extrinsic factors, the operative position was considered first. All our tonsillectomies were performed with the patient in the upright position, and suction was generally used to keep the throat clear. Since only 1 lung abscess occurred in 1654 tonsillectomies, a figure which compares favorably with those of other clinics where the Rose operative position is used, it is difficult to believe that operative position was an important factor. Likewise, the use of suction, which some observers fear may cause more bleeding, and thus indirectly inhalation and an increased risk of thrombosis, is in the main a negligible factor, because if it were not, since it was frequently employed, we should have had many more abscesses than are shown in this investigation.

Preoperative medication in our cases certainly could not be considered a factor, because we used so little sedation. Medication for adults took the form of morphine and atropine. Children received either no medication, or small doses of atropine (1/500 or 1/250 gr.), according to age. Atropine has its proponents, who welcome the lessened secretion in the presence of ether which it causes, and opponents, who fear that although the secretion is lessened, its thickening is a source of danger. It is our experience that atropine is valuable in small dosage, especially when the anesthetic is ether, because it may help to prevent bronchial obstruction and atelectasis. We cannot believe that the viscid secretion it may possibly bring about is as likely to obstruct as is the greatly increased secretion produced by ether without atropine. We do know that in pneumonic processes, where there is considerable secretion present, small doses of atropine are distinctly helpful. The preponderance of opinion does not favor any medication that abolishes laryngeal reflexes.

In considering intrinsic factors, we realized how important was the preoperative condition of the patient. Tonsillectomy is an operation of choice, and is rarely to be considered an emergency. We are convinced that the most potent cause for pulmonary complication is infection already present in the upper or lower respiratory tract before operation. With lowered resistance, and the reactivation of an already present infection to virulence, the complication may be produced. Only re-

LUNG ABSCESS AND ITS RELATION TO SURGERY OF THE UPPER RESPIRATORY TRACT

HYMAN MORRISON, M.D.*

BOSTON

THERE are two modes of approach to the statistical study of lung abscess. The internist sees enough of this disease in the course of years to be profoundly impressed, not only by its seriousness but also by the fact that in many instances it follows some surgical procedure in the region of the mouth, nose or throat, and particularly tonsillectomy. The otolaryngologist, on the other hand, sees in this attitude a challenging implication with which he takes issue.

The otolaryngologist rarely if ever sees lung abscess as a complication in his operative cases. Furthermore, studies of large series of cases show an average incidence of 1 case of lung abscess in 2000 or 3000 cases of tonsillectomy.^{1, 2} Some writers, especially in England, have even found the incidence greater after general operations than after surgery on the respiratory tract. At this point, however, it should be stressed that the important factor is not the ratio of this complication to a given number of operations, of whatever kind, but the very serious fact that in any substantial group of lung-abscess cases, a large proportion occur after operation on the upper respiratory tract, and particularly after tonsillectomy.

The observation of Norris and Landis³ is pertinent to this matter. They say

Although the experience of any one operator, or even that of a large clinic, is limited, the number of cases of abscess following tonsillectomy is in the aggregate quite large. Statements of individual operators that they have never met with this sequel are of doubtful value, and this is especially true of large clinics where the patients are easily lost trace of. It is now known that many of these abscess cases never come to the knowledge of the operator. Some of them are recognized by another physician as abscesses only after months have elapsed.

In 1925, Lord⁴ reported 227 cases of lung abscess observed at the Massachusetts General Hospital between 1909 and 1924. Of these, 96 (42 per cent) followed some operative procedure, 78 (34 per cent) followed some operation on the upper respiratory tract, of which 21 (9 per cent) occurred after the extraction of teeth and 49 (22 per cent) after tonsillectomy, and the remaining 8 followed operation elsewhere. Aspiration of foreign bodies was responsible for 8 cases. There were 28 cases (12 per cent) in this series which were ascribed to

pneumonia. One case followed esophagoscopy, and in the rest the cause was not determined.

In 1934, King and Lord⁵ reported a second series of 210 cases of lung abscess, observed at the Massachusetts General Hospital between 1924 and 1932. While in Lord's earlier series, just mentioned, approximately 1 of every 3 cases could be traced to operations in or near the upper respiratory tract, the proportion in the second series rose to about 1 of every 2 cases (117 cases, or 56 per cent). The operative procedures included the removal of tonsils and adenoids in 81 cases (39 per cent), the extraction of teeth in 26 (12 per cent) and an upper respiratory operation in 10 (4.8 per cent), 19 (9.0 per cent) of the cases were due to other operations under a general anesthetic, making a total of 136 (65 per cent) referable to previous surgical procedures. The remaining cases were less clear, in 48 (23 per cent) the onset was insidious and the cause was undetermined, 17 (8 per cent) suggested pneumonia as a cause, 5 (2 per cent) followed an upper respiratory infection.

In the records of the Beth Israel Hospital there is to date a series of 66 cases of lung abscess. Of these, 34 (52 per cent) came after some surgical procedure, 31 (47 per cent) followed operations on the upper respiratory tract, of which 4 (5 per cent) were the extraction of teeth, and 26 (39 per cent) tonsillectomy. One case followed aspiration of a foreign body, 20 (30 per cent) pneumonia, and the rest miscellaneous conditions, such as the breaking down of carcinoma of the lung, bronchiectasis or some undetermined antecedent condition.

One significant conclusion must be drawn from these figures: surgery of the upper respiratory tract and pneumonia are responsible for most of the cases of lung abscess. The latter condition must be considered in the general problem of pneumonia control. Its incidence following operations on the upper respiratory tract, on the other hand, challenges the serious co-operation of the general practitioner, internist, otolaryngologist, oral surgeon and anesthetist. In fairness it must be admitted that the well-trained otolaryngologist rarely meets this complication. Nevertheless, if from a fifth to a third of all cases of lung abscess follow tonsillectomy, the profession, led by the otolaryngologist, must insist on a better general technic for this and kindred operations.

From the Thoracic Clinic, Beth Israel Hospital, Boston.

removal of an inhaled veal bone, with consequent infection, was the causal factor

FACTORS IN CASES FOLLOWING ABDOMINAL OPERATION

In these cases the important factors are the condition of the patient, both before and during the operation, the anesthesia — predisposition to formation of much mucus and atelectasis, and the operative position — interference with lung ventilation, stagnation of secretions, and predisposition to atelectasis, the length of operation, the infective source, and the postoperative period

These factors are essentially the same as those which are operative in abscesses which follow medical conditions or operations on the upper respiratory tract. The condition of the patient is apparently always the most potent factor. The anesthesia and operation are both of longer duration, the dependent operative position maintained so long, causing interference with lung ventilation and consequent stagnation of secretions, adds to the possibility of atelectasis. Although infarction and embolism are stressed by many, there is much evidence that atelectasis and bronchial obstruction constitute the most frequent cause. Examination of our histories showed 1 possible infarct in a case of tonsillectomy, 1 of definite atelectasis following an appendix operation, 1 of infarct following a gall-bladder operation, 1 of infarct following an operation for gastric ulcer, 1 of infarct following a perineal operation, and 5 of infarct or embolus following gynecologic and obstetric operations. It is possible that there were more infarcts or embolic cases, but there was no evidence to prove their presence. It was only in the gynecologic and obstetric cases that infarct and embolism were prominent, as is the common experience. Most of the other cases more nearly approximated what one would expect to find in atelectatic bronchial obstruction. However, in spite of the fact that the distribution of emboli is often the same as in cases definitely aspiratory, it is reasonable to assume that the peripheral portions of the lung would be more frequently affected in infarction and embolism than those near the bronchi. Nevertheless, those cases with a definite infective source, such as a ruptured appendix or an empyema of the gall bladder, are the most likely ones to develop an infarction or embolus, even though we have been unable to find proof of this in individual cases.

SUMMARY

This investigation represents an analysis of all proved cases of lung abscess occurring at the Boston City Hospital in the years 1926 to 1935, inclusive. There were 196 cases of lung abscess following medical conditions, 4 cases following trauma and 76 cases following postoperative conditions, a total of 276 cases.

Although it has become the general belief that postoperative complications are predominating factors, this was not so in our cases. We believe that a careful investigation in other large clinics would produce results similar to ours. Tonsillectomy is a prominent cause in a large number of cases, largely because it is more frequently performed than any other operation. However, when compared to the total number of operations performed it represents a smaller percentage than is generally realized, and compares favorably not only with the incidence following pneumonia, but also with that following other postoperative conditions.

It is also evident that nearly all the cases of post tonsillectomy lung abscess occur in adult patients, and that they require more careful selection and preoperative care and better postoperative attention than heretofore recognized.

We believe that a more careful examination before all operative procedures and more careful post operative observation will considerably lessen the incidence of postoperative lung abscess.

- 5 Pneumothorax. Often helpful
- 6 Thoracentesis when fluid is present, with histologic study of sediment.
- 7 Thoracoscopy. Limited usefulness
- 8 Needle punch biopsy. Often helpful.

Except for a careful history-taking and a thorough physical examination, x-ray is doubtless the most helpful diagnostic procedure. Unfortunately there are frequent complications which decrease its value. One of these is the presence of effusion in the pleura, which gives a homogeneous density without diagnostic detail.

A boy of eight (Case 1, Fig. 1) had persistent vague symptomatology and a pleural effusion preventing x-ray diagnosis. Removal of approximate-

Bronchoscopy in expert hands is quite harmless and is extremely helpful both in diagnosis and in therapy. In another patient (Case 3), however, diagnostic tissue from the bronchus was unobtainable until a second attempt had been made. Because of this, two other valuable methods of diagnosis were applied. Lipiodol was instilled for a bronchogram, which demonstrated the lesion to be fairly high in the lower lobe bronchus, and a thoracoscope was inserted through a trocar between the ribs for examination and biopsy of the irregular pleural surface. Histologic study of the tissue proved the tumor to be an adenocarcinoma.

Thoracoscopy, although limited in its usefulness,

Figure 1. Case 1. Before and after removal of fluid and reinstallation of air demonstrating large mediastinal tumor.

ly 1600 cc. of fluid with instillation of air enabled the x-ray to reveal a large mediastinal tumor, which was proved at postmortem examination to be lymphosarcoma.

A man of fifty-one (Case 2) complained of cough and malaise for 1 year. Four months previously he had developed dyspnea, and effusion was found. The fluid obscured any underlying lesion, but when it was removed and replaced by air, a tumor of the left lower lobe was revealed, with some irregularity of the pleural surface indicating metastasis.

For either diagnosis or therapy large amounts of fluid can be removed at one sitting if one will equalize the intrathoracic pressure by injecting, almost simultaneously, equivalent amounts of air so that the lung is not rapidly expanded or the mediastinum rapidly shifted. The amount of fluid removed can exceed the amount of air re-injected by about 1000 cc. in the average adult. We have done this on many occasions and have so far seen no ill-effects, other than those which may follow the single insertion of a needle.

is particularly helpful in selected cases. A patient (Case 4) now in the hospital, entered complaining of cough and dyspnea and was found to have a large pleural effusion, when this was evacuated and replaced by air, there was revealed a large carcinomatous infiltration of the anterior wall and diaphragm, originating from a recurrent carcinoma of the right breast removed eight years before. This infiltration also was biopsied through the thoracoscope, since there was no endobronchial tumor to be obtained through the bronchoscope.

TUBERCULOSIS

Unless one can produce closure of cavities in tuberculosis, cure cannot be obtained. Although in many patients this result is achieved by sanatorium care, many others are not so fortunate. Sanatorium care alone is usually quite prolonged and expensive. The principle underlying the surgical attack on tuberculosis is closure of the cavity by the various methods of collapse therapy. Pneumothorax is the simplest and most popular method of producing such collapse, and there are very few

From the point of view of the prevention of lung abscess, several propositions stand out

- 1 Tonsillectomy and other operations on the nose and throat are major surgical procedures
- 2 Such operations should be performed in a

7 Finally, tonsillectomy should not be advised, particularly in adults, without clear and weighty indications. The surgeon and family physician must be sure that the operation is absolutely necessary

hospital, and the cases should be carefully followed

3 Local anesthesia is preferable to general, but more important than the type of anesthesia is the qualification of the anesthetist

4 It goes without saying that the surgeon should be well qualified, and also that he should have his patient physically fit before the operation

5 It is well established that the danger of lung abscess after tonsillectomy is much greater in adults than it is in children

6 The extraction of teeth should be done in several sessions, obviating general anesthesia and too large a wound, and also minimizing the danger of foreign-body aspiration

This discussion merely re-emphasizes what has been taught over and over again. Reiteration, however, will have been justified if it leads in any measure to the prevention of a disease which is so often crippling and even fatal

THE GENERAL PRACTITIONER AND THORACIC SURGERY

W EMORY BURNETT, M.D *

PHILADELPHIA

THORACIC surgery is developing so rapidly at the present time that almost monthly one hears of some new development making possible the control or cure of diseases previously considered unapproachable or inoperable. This branch of surgery is so recent that many physicians have not had the time or the opportunity to acquaint themselves with its accomplishments or possibilities.

It seems a very short time ago that 80 per cent of patients with advanced pulmonary tuberculosis died and 20 per cent recovered. Since the intelligent application of collapse therapy these percentages have been reversed. It is still difficult to convince physicians that surgical drainage of lung abscess will cure many of their patients if

done early enough to avoid the bronchiectasis which accompanies long-standing suppuration. There is work now afoot which, when evaluated, may prove that drainage within the first two or three weeks applied to all lung abscesses will greatly reduce the morbidity and the mortality of this serious disease. This branch of surgery has also made possible the cure of bronchiectasis, and is a possible modicum of control of carcinoma of the lung, though this is not yet proved. The demonstration of a few cases may illustrate some of the possibilities.

DIAGNOSTIC AIDS

Since diagnosis is so essential to proper treatment, a few words on some of its aids will be appropriate. They are as follows:

- 1 X ray. Extremely important and helpful.
- 2 Bronchoscopy. Extremely important.
- 3 Bronchoscopic biopsy when tumor is visible.
- 4 Sputum analysis. Important.

From the Surgical Department Temple University Medical School Philadelphia Pennsylvania

EMPHYEMA

The increasing knowledge of intrathoracic physiology has contributed also to the treatment of empyema. By the older methods of wide and adequate drainage, as many as 30 per cent of simple empyemas may result in death when such wide-open drainage is applied early to a massive effusion, before stiffening of the mediastinum or adhesions of portions of the lung to the chest wall have occurred. Open drainage at this time destroys the negative pressure by which the lung is kept expanded and by which the two sides of the thorax are equalized in pressure. The result is

erations such as extensive thoracoplasties. Such large chronic cavities are practically unknown under this method. In addition, the illness is greatly shortened. It is thus possible to use this method on both sides at the same time, since the respiratory mechanism is continued at an increasingly excellent level. This patient (Case 9, Fig. 4) was so treated for bilateral empyema following bilateral pneumonia. He made an uneventful recovery in spite of the drainage on the two sides within five days of each other, and was discharged five weeks after the second drainage.

In a fair percentage of cases following such closed

A

B

Figure 3 Case 8 A Large cavity left upper lobe and ineffectual pneumothorax B Pneumothorax abandoned and the cavity closed by two-stage thoracoplasty

sudden and complete collapse of the affected side, with attendant dyspnea and anoxemia and movement of the mediastinum with each respiratory effort. This mediastinal flutter causes severe embarrassment to the heart, and we have seen such patients, recovering from their infection, die of the failure of an otherwise normal heart. If, on the other hand, a closed method of drainage is utilized, we maintain equilibrium between the two pleural spaces and a constantly expanding lung. This obviates mechanical difficulties arising immediately after operation, and the lung is pulled out to the chest wall as the pus is evacuated. It adheres shortly after contacting the parietal pleura, thus obliterating the pleural space, and prevents the formation of thick-walled chronic empyema cavities, which necessitate multiple deforming op-

erations, a pocket of loculated empyema results, necessitating a second operation. With such loculated cavities, the lung being adherent to the chest wall about the pocket, open drainage is safe and preferable. If the empyema when first seen is already loculated and fairly small, time is saved by immediate rib resection and open drainage, with the removal of the fibrin clot which is usually present. This was so in Case 10, the patient being discharged three weeks after drainage had been instituted. We consider aspiration valueless except for diagnostic purposes and the misconception, so prevalent in some communities, that repeated aspiration is a conservative and safe treatment of empyema has caused many deaths, countless complications or at best a great increase in morbidity.

who prefer other methods when pneumothorax can be performed. The following patient (Case 5, Fig 2) obtained excellent collapse and permanent cure even after re-expansion. Pneumothorax was begun four months after the onset of a rather acute illness, and was continued for seventeen months. The lung was then allowed to re-expand, and there was no evidence of continuing disease. The patient has been clinically well for about three years. How long such pneumothorax should be

If several adhesions are present in the region of the cavity, pneumothorax is often inadequate or unobtainable. Under such circumstances, paralysis of the phrenic nerve, which allows the diaphragm to ascend into the thorax, relieves the tension upon the lung, and may produce sufficient relaxation to allow closure of the cavity. Unfortunately this method is frequently ineffective, often produces considerable dyspnea, and interferes with effective expectoration. For these reasons thoracoplasty is

Figure 2. Case 5. *A* Before pneumothorax multiple cavitation of the right upper lobe. *B* Five months later, selective pneumothorax with complete collapse of right upper lobe and only partial collapse of right lower and middle lobes.

continued and whether it should ever be abandoned are controversial subjects. Certainly it should not be terminated in less than three years, and present opinion seems to favor continuing it as long as possible. Unfortunately, in many cases the pleural space is gradually obliterated by adhesions in spite of all efforts to maintain the pneumothorax.

Frequently pneumothorax can be only partially obtained because of adhesions from the chest wall to the lung around the cavity, which hold it open. If the cavity shows fairly thin walls and the adhesions are long and tenuous, they can be cut by thoracoscopic technic without opening the chest. The result of such intrapleural pneumolysis is illustrated by Case 6, that of a young woman who had had pneumothorax for nine months, with continued productive sputum and only moderate general improvement. Following severance of the adhesions there was rapid improvement, the sputum became negative within two weeks, and the cavity closed. Seven months later she was clinically well, showed no cavity and was going about her usual household duties, returning every two weeks for pneumothorax refills.

usually preferred. If phrenic surgery is attempted, it should be done as a temporary measure, and should consist in crushing the phrenic nerve, which will paralyze it for from three to nine months. If this procedure is ineffective or harmful, the paralysis is temporary, if, on the other hand, it is effective and too brief, the nerve can be removed at a subsequent operation in order to induce permanent phrenic paralysis. The patient in Case 7 was ill for one year and was unsuccessfully treated with pneumothorax. Her sputum was negative within two months after phrenic surgery, and she has been clinically well for four years.

As a rule, when pneumothorax is ineffectual, thoracoplasty, either partial or complete, is the procedure of choice, enough of each rib overlying the involved area should be removed to produce collapse of the chest wall sufficient to close completely the underlying cavities. This patient (Case 8, Fig 3) obtained such a result and a clinical cure six weeks after thoracoplasty. This was done in two stages, six ribs being removed and the function of the uninvolved lower portion being preserved.

patient has continued his usual activities in excellent health

Almost always if such drainage is delayed for several months, and occasionally even when it is instituted fairly early, there has been so much destruction of lung tissue and so much bronchiectasis that the lobe or even the whole lung is destroyed, and lobectomy or pneumonectomy is the only possible means of cure

BRONCHIECTASIS

At any age, chronic cough, with profuse expectoration and physical signs of moisture in certain parts of the bronchial tree, with or without

tion later in life leaves the patient with typical bronchiectatic symptoms. Many other cases develop from continued respiratory infection, such as a chronic sinusitis or even tuberculosis. Any condition producing prolonged lavage of the bronchi by purulent material may induce bronchiectasis

Although we have never seen a patient with this disease permanently cured by any means other than surgery, occasionally for fairly long periods such cases may be made symptom-free by bronchoscopy, postural drainage, supportive measures, vaccines and so forth. Nearly always, however, the next respiratory infection brings a recurrence of the

Figure 5 Case 13 A Some increase in peribronchial density, but insufficient to diagnose bronchiectasis B Explanation by lipiodol instillation C Eleven weeks after left lower lobectomy under local anesthesia Lipiodol reveals a normal bronchial outline in an emphysematous left upper lobe and the stump of the left lower lobe bronchus filled with lipiodol

hemoptysis, fever, toxemia or signs of complications, are frequently caused by bronchiectasis or tuberculosis. Such patients often reveal no physical signs of consolidation, and even x-ray, unaided, may not suffice to show the true condition. Without the assistance of opaque material, such as lipiodol, to delineate the size and shape of the bronchi, the diagnosis will often be missed. In Case 13 (Fig 5), one sees few abnormalities in the first film, and no more were shown until the lipiodol was instilled. This is mainly because the area which might have shown induration is obscured by the cardiac silhouette. The etiologic factor in this case was a tonsillectomy done four years previously, but many such cases are congenital, and show no symptoms until some respiratory infec-

tion later in life leaves the patient with typical bronchiectatic symptoms. Many other cases develop from continued respiratory infection, such as a chronic sinusitis or even tuberculosis. Any condition producing prolonged lavage of the bronchi by purulent material may induce bronchiectasis

BRONCHIOGENIC CARCINOMA

The supposedly rare condition of bronchiogenic carcinoma of the lung is found upon study of both postmortem and hospital admission statistics to occur in approximately 10 per cent of all cases of carcinoma. It therefore behooves us to keep it constantly in mind, especially since the symptoms

LUNG ABSCESS

Although the percentage of lung abscesses among the patients of any one doctor or hospital is small, the lesion is important because of its serious character and the high probability that it will become chronic and extremely debilitating, if not fatal.

In spite of experimental evidence to the contrary, the majority of lung abscesses appear to be due to various forms of aspiration of infectious or irritating material. Consider the patient who, under general anesthesia, inspires vomitus, blood, pus,

it is effected by means of a large opening which furnishes adequate drainage, the patient has a good resistance to the infecting organisms, and there is a complete liquefaction of the destroyed tissue. These conditions are conducive to spontaneous recovery, which occurs in approximately one third of all cases. In Case 11, the patient showed definite improvement in two weeks and a complete cure in six weeks from the time the abscess was discovered. If there is no definite improvement in two months from the time of dis-

Figure 4 Case 9 Before and three weeks after simultaneous drainage of bilateral empyema

tissue or some other foreign body while the protective cough reflex is abolished. Other sources of unconsciousness, such as drunkenness, trauma, drugs and even, rarely, natural sleep may permit aspiration similar to that under anesthesia. Following any such a period of unconsciousness we may have the onset of cough, fever and pain in the chest, with physical signs of consolidation, followed in two or three weeks by the profuse production of foul-smelling sputum as the abscess breaks into a bronchus.

Other etiologic factors fairly commonly observed are respiratory infection, such as bronchitis or pneumonia, which fails to clear up, infected emboli from other sources, which occasionally lodge in the vessels of the lung and start an abscess about them, and, rarely, trauma such as that caused by a gunshot or stab wound.

In any case, the great majority of patients presenting this picture fall into three main classes (1) When evacuation into the bronchus occurs,

covery, further delay in obtaining drainage by surgery seriously jeopardizes the patient's chances for recovery, for spontaneous cure is almost never obtained, and a constant absorption of toxic material causes progressive debilitation, while the lesion frequently spreads to adjacent parts of the lung because of recurrent temporary blockage of the drainage aperture. (2) Bronchoscopic aspiration and postural drainage, combined with blood transfusions and other supportive measures, may increase the percentage of nonsurgical cures from 30 to 40 or 45. (3) Of the remaining 60 or 55 per cent of these chronic and long standing abscesses, adequate surgical drainage may cure an additional 20 or 25 per cent. An example of the excellent response to drainage is furnished by Case 12, in which surgery was not postponed too long. The patient was completely well in ten weeks, although he had been ill for five months before drainage. A film taken one year later showed no evidence of recurrence, and the

THE CLASSIFICATION AND TREATMENT OF ARTHRITIS

DENIS S. O'CONNOR, M.D.*

NEW HAVEN, CONNECTICUT

THE two most important factors underlying the confused state of mind of the medical profession in regard to arthritis are first, the lack of a universally understandable etiologic classification, and secondly, a failure to understand the pathologic process which goes on in the joint tissues in response to irritation. If a classification based on the pathologic processes in the joints gave any adequate idea of the processes themselves, it would serve admirably and the confused state of mind would cease to exist. The fact that arthritis is so poorly understood, even at the present time, is convincing evidence that pathologic classifications have failed. The etiologic classification here presented has been used in instructing nurses and medical students concerning arthritis, with a resultant grasp of the subject which is most encouraging, considering the difficulty experienced with the prevailing classifications.

This classification is based on the theory that there are three basic etiologic factors in arthritis: bacteria, toxins and trauma. It is well known that bacteria may exert their deleterious effects upon tissues in two ways: first, by invasion of the joint tissues, and secondly, by the poisonous effects of the products of bacterial metabolism. The latter does not require the presence of the bacteria in the joint tissues, and the source of production of the poisons—the focus of infection—may be in a distant part of the body. If the bacteria are present in the joint tissues, both bacteria and the products of their metabolism operate, but the effects of the former are so much more severe than those of the latter that the latter are submerged.

The very fact that no distinction is made between direct invasion and poisoning by bacterial products constitutes a predominant source of confusion in the understanding of arthritis, and the principal bar to proper treatment. The effects cannot be the same. The presence of bacteria in the joint tissues calls forth the white blood cells, principally the polymorphonuclears, to combat the invasion. The proteolytic enzymes elaborated by these cells bring about the liquefaction of tissues, which are destroyed in the inflammatory process. The destructive action in infection is in inverse proportion to the intimacy of blood supply to the tissues and in direct proportion to its lack. The articular cartilage, having a very feeble blood supply, has little if any defense against the destructive action of the proteolytic enzymes and is an easy prey. Bac-

terial poisons, on the other hand, call out very little polymorphonuclear reaction, and the tendency to destructive liquefaction of the cartilage is consequently less.

Thus, destructive action on the cartilage—the essential joint tissue—and its inability to regenerate are fatal to the joint as a moving mechanism. Between the extremes of virulent bacterial invasion and bacterial toxic damage are gradations of joint damage depending upon the polymorphonuclear reaction developed. In the classification here presented, "infectious" has been made one of the main headings, this group has been subdivided into "bacterial" and "toxic," so as to recognize the production of joint damage by direct bacterial reaction and by the toxic action of bacterial products.

In bacterial arthritis, a focus of infection in another part of the body is of minor importance, since the establishment of the bacteria in the joint tissues constitutes an autonomous focus. Knowledge that the bacteria have invaded the joint is therefore of major importance, as is recognition of the particular organism and its characteristics. In toxic arthritis with an infectious basis—the focal-infection type—it is necessary to locate the focus of infection in order to recognize the organism. Elimination of the focus will contribute much to improving the condition, but the degree of improvement and the period of time necessary for it to take place depend upon how long changes in the joints had existed before the focus was removed, and the care of the joints during the active infection. Furthermore, discovery of a focus of infection does not necessarily mean that it is the sole or even partial cause of the arthritis.

It often happens that the focus is so located that it cannot be eliminated, and to minimize the effects of this infection will often tax one's ingenuity. The question may also be raised in so-called focal infection whether foci are the causes of the joint affection, or merely manifestations of a lowered resistance to infection. Even when improvement in the joints soon follows elimination of a focus, the latter is not necessarily the cause of the arthritis, since it may well be considered an overload on the body economy, the removal of which placed the body mechanism in a better position to combat the joint condition.

All arthritis is not caused by infection, and all toxins are not the product of bacterial action. In order to include those causes which do not arise

*Assistant clinical professor of orthopedic surgery, Yale University School of Medicine; attending surgeon, New Haven Hospital.

of the early stage are extremely vague. The only constant symptom is that of mild cough, which is usually disregarded by the patient and even by the physician. Thus it appears essential that wherever a persistent cough, especially in a person above thirty-five, does not respond to active treatment, the case be investigated to the limit of our diagnostic ability before carcinoma is excluded.

Figure 6 Case 14 A medium sized tumor of left upper lobe revealed following a diagnostic pneumothorax

Hemoptysis from ulceration of the tumor also may occur fairly early. However, atelectasis, pain in the chest and pleural effusion, any one of which may cause the patient to seek aid, usually indicate an advanced involvement, and such cases often prove inoperable. Frequently it is impossible to know the operability of such a lesion without thoracic exploration. We have explored 9 such cases and found only 1 operable. This patient (Case 14, Fig 6) was only twenty-seven, and was

first thought by his physician to have a bronchiogenic spread of tuberculosis from a peribronchial lymph node. Thus considerable time was wasted, and the very cellular cancer grew rapidly until lobectomy was performed, seven months after the first complaint of cough and hemoptysis. The patient made an uneventful recovery from the lobectomy, but because of our mistaken conservatism in removing only the involved lobe and not the entire lung and mediastinal lymph nodes, he returned in four months with recurrence in the lower lobe at the hilus of the removed upper lobe. A second attempt was made to complete the pneumonectomy and remove the tumor, but it was so soft, rapidly growing and extensive that the operation had to be abandoned. He was treated by heavy doses of x-ray therapy without effect, and the patient died eighteen months later.

In spite of the marvelous results obtained by x-ray in many carcinomatous lesions, no proved case of bronchiogenic carcinoma has ever been cured by this method, and as a rule the effect upon the tumor is so slight that it does not compensate for the sickness which so frequently accompanies heavy dosage. The only benefit we have seen has been that of the abolition or decrease of pain.

Although it is too early to evaluate the results from surgery, several articles by Graham, Sauerbruch, Churchill, Edwards, Allen and Smith, Overholt and Rienhoff report upward of a dozen cases alive and apparently well for more than six months. Two of these have been observed for three years after operation, 3 for two years and 2 for one year. Thus one can visualize the probability that earlier diagnosis made by alert physicians, who will urge radical surgery upon such patients as their only hope of cure, may eventuate in a measure of control of bronchiogenic carcinoma similar to that of cancer in other parts of the body.

3701 North Broad Street.

tious since the symptoms and signs are those of infection and the trauma is incidental. After an infectious lesion has occurred in a joint without obvious damage, the mechanism of the joint is often sufficiently disturbed so that with ordinary use changes will arise which must be classified as traumatic. The presence of toxic factors in the body in conjunction with the abnormal use of a joint results in earlier or more pronounced changes of a traumatic nature, and the condition is to be accordingly classified.

A classification is not a substitute for reasoning, it is a logical and convenient arrangement based upon knowledge of the subject, and as such is presented in Table 1

* * *

Arthritis, whether it be acute or chronic, is a painful disease. It interferes with, if it does not prevent, normal activity of the body, and it constitutes a threat to joint motion. For these reasons it requires positive and intelligent treatment, which in turn demands a complete understanding of the factors behind the arthritic process.

As stated above, there are three principal foes to normal joint function: bacteria, poisons and trauma. While any one of these may act alone to produce joint lesions, it is more likely that two or even all three will act in a given case. All the possible combinations of these three factors cannot be considered in a short article, and it is doubtful whether even a fair-sized volume could cover the large number of ways in which the three may interact. We shall discuss the treatment of the pure arthritic types, but the practitioner must combine with these conclusions his study of the individual case.

BACTERIAL ARTHRITIS

The indefinite term "infectious arthritis" has come to convey different impressions to different people. The term "bacterial arthritis" is used here to denote any arthritis caused by invasion of the joint structures by bacteria. How is bacterial invasion to be determined? For the time being, only recovery of the bacteria from the joints affected can be considered scientific proof, although clinical judgment may at times determine the matter without resort to identification of the organism. If the organism be the tubercle bacillus, the treatment must be limited to what the patient is willing to accept. At present, permanent control of the tuberculous process is possible only through the destruction of the joint. Retention of varying amounts of joint function with subsidence of the tuberculosis is possible, but the reactivation of the tuberculous process is a constant threat.

Luetic arthritis, like syphilis in any part of the

body, is susceptible to general treatment by specific drugs, but the time element here is as important as in any invasion of the joint, that is, procrastination may result in permanent joint damage even though the luetic process is eventually brought under control by antiluetic drugs.

For practical purposes, all the pus-producing organisms can be considered in a group. Invasion of a joint by any one of them may result in an inflammatory reaction, varying from a serous joint effusion to a fulminating purulent one. Destruction of cartilage, the tissue peculiar to the integrity of the joint, is accomplished by the proteolytic enzymes elaborated by pus cells. The number of pus cells present, determining as it does the concentration of enzymes, is an important indication of the degree of danger to the cartilage. Three stages of severity are recognized: serous, seropurulent and purulent types.

In the *serous* type the invading organism calls forth little cellular response and the joint fluid contains a relatively small number of pus cells. There is relatively little danger of marked destruction of the cartilage. Clinically, there is only a slight rise of temperature, and the white-cell count and polymorphonuclear percentage of the blood are only moderately increased. Surgery is seldom necessary. A well-molded plaster cast, and measures aimed at building up quickly the patient's resistance, are usually sufficient to turn the tide. Even in this mild type of arthritis a close watch must be maintained to see that the condition does not develop into either of the more serious types. The temperature trend and the white-cell count and polymorphonuclear percentage must be watched closely.

In the *seropurulent* type, the number of pus cells in the joint effusion is sufficient to give it a thin, purulent character. With such a concentration of cells, one must be prepared for radical surgery, and resort to it without hesitation if the temperature trend is unfavorable and the white-cell count and the polymorphonuclear percentage tend to rise. The seropurulent type does not always require surgical measures, but until one has had considerable experience, the surgical approach is probably the safest for the preservation of the cartilage. It must always be borne in mind that the serous and seropurulent types may be early stages in the highly dangerous purulent type, but that the process may stop before reaching the last-named stage.

The *purulent* type invariably represents a fulminating infection or a late recognition of a joint invasion. The patient's life is endangered, and the damage to the joint cartilage is of secondary consideration. Treatment aimed at saving the patient

from infections, and to devalue the overwhelming importance which has been ascribed to infection since the promulgation of the theory of focal infection, the other main heading in this classification has been designated as "noninfectious." The principal subdivision under this heading is "toxic." This term is a logical and desirable one. Under it can be placed the many diverse and seemingly unrelated causes of arthritis which are gaining adherents with the development of our knowledge concerning the abnormal actions of various glands in the body, and with the discovery of the effects on the body of poisons originating outside it. Since this classification, if it finds favor, must serve in the investigation of arthritis as well as act as a convenient clinical guide, the term "toxic" requires further subdivision, according to whether the toxins arise within or outside the body. The term "endogenous" includes those conditions other than infection which within the body give rise to toxic products. The terms "allergic," "metabolic," "climacteric" and many others which have no logical place in any existing classification may be readily placed in this division as "glandular dysfunction" or "intestinal dysfunction," without doing violence to our classification.

"Exogenous" poisons include those arising outside the body but taken into it accidentally,—through environment or industrial exposure,—or intentionally,—as food or medicine,—without knowledge of their poisonous effects on the joints. Arthritis and arthritic symptoms are not always primary, but may be secondary to disturbance of the muscular control of the joints from various causes. If the cause of the disturbance be unknown, the latter would be considered the etiologic factor, and the joint condition is to be classified under the second subheading "noninfectious, traumatic," the subclassifications of which will be discussed later. But if the cause is known to be chronic lead poisoning, for instance, the arthritis is to be classified under "noninfectious, toxic."

Trauma, the third important etiologic factor, finds a logical place under the heading "noninfectious." All joints are not equally subject to trauma, but that trauma is a cause of arthritis needs no demonstration. It is rather the definition of just what constitutes trauma that requires explanation. The joints suffer trauma in their ordinary use. Without any specific trauma, the joints after many years show certain changes which are designated as hypertrophic arthritis. Certain factors tend to bring these changes about at an earlier age than they would ordinarily occur. Just when they are to be considered normal and when pathologic cannot be stated here, but the age of the person affected and the extent of their development determine their abnormality.

Habitual variations from the normal physiologic posture continued over a long period—faulty posture—result in strain of the joint structures, giving rise to changes and symptoms before they would normally be expected. Such trauma is classified as "physiologic." If, in the performance of a particular occupation, one or several joints are brought into use repeatedly many times a day for a long period, the joints so used will show a greater development of abnormal changes than others. This type of trauma is designated as "occupational." If, as the result of a violent injury to the structures about a joint, its normal relations are disturbed, the eventual changes and symptoms are designated as "accidental."

For ordinary clinical use, the classification as outlined is no doubt too detailed. By judicious elimination and consolidation, it can be reduced to the three essential etiologic factors from which we started.

It should not be inferred that any case of arthritis will be confined in its etiology to any one or even two of the factors given. No one with an adequate present-day understanding of arthritis expects to see many cases of a single type. Trauma is frequently a localizing factor in a bacterial arthritis, but the latter is classified as infec-

tious since the symptoms and signs are those of infection and the trauma is incidental. After an infectious lesion has occurred in a joint without obvious damage, the mechanism of the joint is often sufficiently disturbed so that with ordinary use changes will arise which must be classified as traumatic. The presence of toxic factors in the body in conjunction with the abnormal use of a joint results in earlier or more pronounced changes of a traumatic nature, and the condition is to be accordingly classified.

A classification is not a substitute for reasoning, it is a logical and convenient arrangement based upon knowledge of the subject, and as such is presented in Table 1

* * *

Arthritis, whether it be acute or chronic, is a painful disease. It interferes with, if it does not prevent, normal activity of the body, and it constitutes a threat to joint motion. For these reasons it requires positive and intelligent treatment, which in turn demands a complete understanding of the factors behind the arthritic process.

As stated above, there are three principal foes to normal joint function: bacteria, poisons and trauma. While any one of these may act alone to produce joint lesions, it is more likely that two or even all three will act in a given case. All the possible combinations of these three factors cannot be considered in a short article, and it is doubtful whether even a fair-sized volume could cover the large number of ways in which the three may interact. We shall discuss the treatment of the pure arthritic types, but the practitioner must combine with these conclusions his study of the individual case.

BACTERIAL ARTHRITIS

The indefinite term "infectious arthritis" has come to convey different impressions to different people. The term "bacterial arthritis" is used here to denote any arthritis caused by invasion of the joint structures by bacteria. How is bacterial invasion to be determined? For the time being, only recovery of the bacteria from the joints affected can be considered scientific proof, although clinical judgment may at times determine the matter without resort to identification of the organism. If the organism be the tubercle bacillus, the treatment must be limited to what the patient is willing to accept. At present, permanent control of the tuberculous process is possible only through the destruction of the joint. Retention of varying amounts of joint function with subsidence of the tuberculosis is possible, but the reactivation of the tuberculous process is a constant threat.

Luetic arthritis, like syphilis in any part of the

body, is susceptible to general treatment by specific drugs, but the time element here is as important as in any invasion of the joint, that is, procrastination may result in permanent joint damage even though the luetic process is eventually brought under control by antiluetic drugs.

For practical purposes, all the pus-producing organisms can be considered in a group. Invasion of a joint by any one of them may result in an inflammatory reaction, varying from a serous joint effusion to a fulminating purulent one. Destruction of cartilage, the tissue peculiar to the integrity of the joint, is accomplished by the proteolytic enzymes elaborated by pus cells. The number of pus cells present, determining as it does the concentration of enzymes, is an important indication of the degree of danger to the cartilage. Three stages of severity are recognized: serous, seropurulent and purulent types.

In the *serous* type the invading organism calls forth little cellular response and the joint fluid contains a relatively small number of pus cells. There is relatively little danger of marked destruction of the cartilage. Clinically, there is only a slight rise of temperature, and the white-cell count and polymorphonuclear percentage of the blood are only moderately increased. Surgery is seldom necessary. A well-molded plaster cast, and measures aimed at building up quickly the patient's resistance, are usually sufficient to turn the tide. Even in this mild type of arthritis a close watch must be maintained to see that the condition does not develop into either of the more serious types. The temperature trend and the white-cell count and polymorphonuclear percentage must be watched closely.

In the *seropurulent* type, the number of pus cells in the joint effusion is sufficient to give it a thin, purulent character. With such a concentration of cells, one must be prepared for radical surgery, and resort to it without hesitation if the temperature trend is unfavorable and the white-cell count and the polymorphonuclear percentage tend to rise. The seropurulent type does not always require surgical measures, but until one has had considerable experience, the surgical approach is probably the safest for the preservation of the cartilage. It must always be borne in mind that the serous and seropurulent types may be early stages in the highly dangerous purulent type, but that the process may stop before reaching the last-named stage.

The *purulent* type invariably represents a fulminating infection or a late recognition of a joint invasion. The patient's life is endangered, and the damage to the joint cartilage is of secondary consideration. Treatment aimed at saving the patient

from infections, and to devalue the overwhelming importance which has been ascribed to infection since the promulgation of the theory of focal infection, the other main heading in this classification has been designated as "noninfectious." The principal subdivision under this heading is "toxic." This term is a logical and desirable one. Under it can be placed the many diverse and seemingly unrelated causes of arthritis which are gaining adherents with the development of our knowledge concerning the abnormal actions of various glands in the body, and with the discovery of the effects on the body of poisons originating outside it. Since this classification, if it finds favor, must serve in the investigation of arthritis as well as act as a convenient clinical guide, the term "toxic" requires further subdivision, according to whether the toxins arise within or outside the body. The term "endogenous" includes those conditions other than infection which within the body give rise to toxic products. The terms "allergic," "metabolic," "climacteric" and many others which have no logical place in any existing classification may be readily placed in this division as "glandular dysfunction" or "intestinal dysfunction," without doing violence to our classification.

"Exogenous" poisons include those arising outside the body but taken into it accidentally—through environment or industrial exposure,—or intentionally,—as food or medicine,—without knowledge of their poisonous effects on the joints. Arthritis and arthritic symptoms are not always primary, but may be secondary to disturbance of the muscular control of the joints from various causes. If the cause of the disturbance be unknown, the latter would be considered the etiologic factor, and the joint condition is to be classified under the second subheading "noninfectious, traumatic," the subclassifications of which will be discussed later. But if the cause is known to be chronic lead poisoning, for instance, the arthritis is to be classified under "noninfectious, toxic."

Trauma, the third important etiologic factor, finds a logical place under the heading "noninfectious." All joints are not equally subject to trauma, but that trauma is a cause of arthritis needs no demonstration. It is rather the definition of just what constitutes trauma that requires explanation. The joints suffer trauma in their ordinary use. Without any specific trauma, the joints after many years show certain changes which are designated as hypertrophic arthritis. Certain factors tend to bring these changes about at an earlier age than they would ordinarily occur. Just when they are to be considered normal and when pathologic cannot be stated here, but the age of the person affected and the extent of their development determine their abnormality.

Habitual variations from the normal physiologic posture continued over a long period—faulty posture—result in strain of the joint structures, giving rise to changes and symptoms before they would normally be expected. Such trauma is classified as "physiologic." If, in the performance of a particular occupation, one or several joints are brought into use repeatedly many times a day for a long period, the joints so used will show a greater development of abnormal changes than others. This type of trauma is designated as "occupational." If, as the result of a violent injury to the structures about a joint, its normal relations are disturbed, the eventual changes and symptoms are designated as "accidental."

For ordinary clinical use, the classification as outlined is no doubt too detailed. By judicious elimination and consolidation, it can be reduced to the three essential etiologic factors from which we started.

It should not be inferred that any case of arthritis will be confined in its etiology to any one or even two of the factors given. No one with an adequate present-day understanding of arthritis expects to see many cases of a single type. Trauma is frequently a localizing factor in a bacterial arthritis, but the latter is classified as infec-

ly toward internal glandular factors as included in the etiology of ankylosing arthritis of the spine.

Diet Faulty nutrition, whether arising from poverty, ignorance of proper diet, faulty metabolism or unwisely attempted control of body weight, is a bar to recovery from arthritis, and in some cases may well be considered a cause of it. All too often, restricted diets as part of the treatment of arthritis aggravate the disease which they are intended to relieve.

Fatigue Either mental or physical fatigue must not be permitted. It is often one of the symptoms in toxic arthritis, and calls for complete rest until it disappears.

Exogenous Poisons These may be classified according to their method of ingress, or according to their origin. The latter classification will be used here. We are not so much concerned with acute, spectacular poisoning, which is seldom a factor in the causation of arthritis, as with slow, insidious poisoning recognized by its remote results rather than by its alarming symptoms.

Diets, or special groups of foods, have always been a favorite method for the treatment of arthritis, and never more so than at the present time. It seems as though every possible combination of food had been recommended for the arthritic, on the other hand, all classes and many individual foods have been banned as inimical to his welfare. Foods vary in digestibility, in their bulk or lack of bulk, and in their nutritive value, but they are all foods. The reaction of the body to them varies, and when a food causes a skin eruption, diarrhea, nausea or any other untoward symptom it is a poison to the body. It is called an "allergic substance" and the reaction is called "allergy." The term "allergic arthritis" has found some acceptance but should be shunned because by derivation it explains why something is poisonous instead of naming the cause. The fact that a given food is poisonous to an arthritic patient is sufficient reason to exclude it from his diet. It is not always possible to show a direct connection between the food poison and the arthritic symptoms, nor is this essential, since the poison concerns us as a factor unfavorable to recovery rather than as a cause. Tomatoes, strawberries, certain shellfish and various meats are not tolerated by certain individuals. It therefore devolves upon the physician to check carefully the patient's reaction to the various classes of foods, and to certain foods in particular.

Drugs which include an ever-widening list of chemical substances and compounds, must have the same close scrutiny as must foods. The pa-

tient is not so apt to sense the relation of medicine to dysfunction as he does that of foods. Insulin, not properly a drug but a biologic product, has been known to cause secondary arthritis.

In *industrial poisons* we again have a group of substances in which the relation to illness is not immediately apparent. The individual may come into contact with the substance in industry or through use of a manufactured product containing it. Lead has been found to be a cause of arthritis, as have arsenic and radium.

Restoration of Normal Physiology

While this second objective in the treatment of toxic arthritis must sometimes await removal of the unfavorable factors, in many cases restoration of the various disturbed functions of the body cannot be begun too early. Reliance upon the well-known tendency of the body to resume its normal state after the elimination of disturbing elements has caused many failures in the treatment of chronic diseases. The toxic arthritic is invariably subnormal in weight, and a trend toward normal is one of the best indications of his improvement. "Chronic indigestion" and "dyspepsia" are often but the outward manifestations of a subnormally functioning digestive system. At the beginning of treatment, the patient cannot copy the diet of the normal person, either as to quality or as to quantity. Small, frequent, highly nutritious and easily digestible meals should be the rule, with a gradual return to normal food habits. In patients who are overweight, restriction of carbohydrates is generally recommended.

Elimination through the intestinal organs suffers with the disturbances of the gastric organs and the limitation of general activity. The proper method for such elimination varies with each case. Abdominal massage and colonic irrigation are used in patients with intestinal organs severely deranged, but these must be looked upon as emergency measures, to be dispensed with in favor of milder means at the earliest possible time. The proper selection of cathartics and laxatives is difficult in the face of the glowing promises made for an increasing number of advertised preparations. The physician should familiarize himself with a few good laxatives, and stick to them.

Exercise is extremely important and is, incidentally, a step toward the return to normal bowel habits. The skeletal muscular system of the body, as well as the muscle of many vital internal organs, loses tone and strength in a chronic illness imposing long inactivity. Restoration can come only from careful and systematic training and the physician could profitably imitate the athletic trainer in his efforts toward their end. Appropriate exer-

serves also to preserve the cartilage. The evacuation of the pus in the joint is essential.

Before undertaking the surgery of infected joints one should study the anatomy of the surrounding structures in order that good drainage, with minimal structural damage and maximal conservation of future function, may be attained. True joint invasions are essentially acute and self-limiting. A distinction should be made between an actively infected joint and one damaged by infection. The end result of infection may be ankylosis by bone or by fibrous tissue, or motion of varying degrees with a mechanically imperfect joint.

TOXIC ARTHRITIS

Arthritis due to poisons may be acute or chronic. The poisons, or toxins, may arise from bacterial invasion in other parts of the body, that is, focal infections, from nonbacterial sources within the body, that is, intestinal and glandular dysfunctions, or from without the body, that is, from foods, drugs, biological preparations or industrial poisons. Arthritis arising from these causes supplies a large group of poorly understood and, so, poorly treated cases. The disease may be primary, directly affecting the joint, or secondary, through disturbance of joint control by the muscles. Because these poisons are general in their action, the affection of the joint may be one manifestation of the toxic effects, or it may be the result of disturbances to other body functions. While the joint must be protected during the activity of the disease process, so as to conserve its function against the time when the disease process will no longer be active, treatment of the disease itself is a problem of internal medicine, and a complicated one.

It would be of small value to describe specific measures of treatment. Each physician has his favorite preparations which seem in his hands to give the most satisfactory results. It is more important to understand the main objectives of treatment, in the order of their importance.

Elimination of Unfavorable Factors

Unfavorable factors may be etiologic elements, and should therefore be eliminated. But even though they are not causative, if they are unfavorable to the body economy they are hindrances to the return of the body to normal, and must be either done away with or minimized as the first step in treatment.

Focal Infection This is unquestionably an important factor, and one which has received much attention—to the detriment of other factors—since the theory of focal infection was advanced. In a very narrow sense it has been looked upon as the one element which must be found in every case of arthritis. Infection in the teeth

and tonsils, because of their easy accessibility, has resulted in their promiscuous removal, often without sound reasons. Infection in the sinuses, the gall bladder, the prostate and the salpingian tubes has received some consideration, but because of the greater difficulty in obliterating them, these organs have failed to become recognized as causes of arthritis. However, these and many other active infections in the body, such as pulmonary tuberculosis and chronic cystitis, may be unfavorable focal infections, treatment of which is necessary if the arthritic process is to be brought under control.

Intestinal Dysfunction It is of course possible to have a focus of infection in the intestinal tract, such as colitis, which can and does cause arthritis, but even without definite infection, faulty functioning of the intestinal tract may be an unfavorable or even a causative factor in toxic arthritis. The end products of digestion may be thought of as having a normal consistence. If those products are retained in the colon beyond a reasonable time, the consistence increases, indicating that some of the fluid has been absorbed. It does not seem likely that the fluid is absorbed as distilled water, nor that only beneficial products are contained in the solution absorbed. It goes without saying that provision has been made within the body for the removal of deleterious substances absorbed from the intestinal tract, but the detoxicating agency may be operating in a faulty manner. Granting such a train of events, it is not difficult to understand how the intestinal tract may be an unfavorable factor.

Glandular Dysfunction The glands of internal secretion have profound effects on all body functions. In our present state of knowledge concerning these glands, one can only say that glandular imbalance, in the form either of an excess or a deficiency, may vitally affect the body mechanism, in a way which we as yet understand only imperfectly, in spite of the startling discoveries of the last ten years. When the internal glandular functions and their effects are more clearly understood, we shall be able to treat some types of toxic arthritis more effectively. Today it is known that the exhausted patient with hyperthyroid disease and the lethargic and overweight hypothyroid individual may both suffer from joint difficulty; the basic answer in either case is regulation of the thyroid function. The coincidence of joint difficulty at onset with the natural or artificial production of the menopause is so well recognized that the term "climacteric arthritis" has been used to describe the condition, and ovarian substance has been found beneficial. Some evidence points clear-

drawbacks The metal springs apparently siphon off the heat produced by the body, giving the patient a feeling of chilliness which may be serious and certainly is not conducive to restfulness Bed rest in itself does not insure rest for an injured or diseased spine. Those who have studied the sleeping human being have reported that the subject frequently changes his position With each change the muscles controlling the spine must change to accommodate to the new position If the patient remains in one position for several hours, he is sure to feel stiff and uncomfortable In either case, rest is not obtained If the spine itself requires rest, a plaster-of-Paris shell made to conform to the natural curves of the body is most effectual Rest for the various muscles is ordinarily obtained by frequent changes of position, in the shells, however, the muscles are not strained and change of position is not essential

To obtain rest for a part of the body or a single joint, properly made casts, splints or braces are used The good which these devices can accomplish is limited by the intelligence and skill behind their application Too often this step is delegated to inexperienced house officers while the designing of braces and corsets is left to brace-makers and corsetières, who, however competent in their own fields, cannot be presumed to understand the surgical conditions for which their apparatus is to be applied The fitting of appliances such as braces and corsets should be closely supervised by the physician, and if he is not competent he should call in a consultant who is

Exercise may be classified as general or local and as active or passive Here is another field in which the average physician is poorly equipped His advice is usually to "take some exercise," but he does not lay down the particulars of the exercise, and experience shows that the patient is not a good judge of the type or amount of exercise, any more than he is competent to prescribe the dosage of morphine or digitalis The judicious combination of exercises of graduated degrees of difficulty within the fatigue limits of the muscles brings the best results

Motion may be relaxed, passive or active Relaxed motion is that type in which the muscles of the part itself are inactive but the action of gravity is used to give motion to the part Passive motion is that type in which a force other than that of the patient's own muscles brings about motion of the part Active motion is that in which the muscles designed to do the particular movement perform the act

Passive motion is usually the first step Active assisted motion, a combination of active and passive, is the second Active motion is the third,

active resisted motion is the fourth, and gives the highest degree of exercise Exercises are frequently begun with the body horizontal or reclining, then in the sitting position, and finally in the vertical or standing position Some mechanical aids are invaluable in bridging the gap between inactivity and normal activity The stationary bicycle for the knees and legs, the rowing machine for the back, the sewing-machine treadle for the feet, marbles for the feet and the collapsible rubber ball for the hands are a few of the simple and more readily available aids The value of exercise for recovery of function lies not in its vigor or the time given to it, but in the regular and systematic performance of each exercise prescribed The physician should change the exercise as often as necessary to meet the development of muscles, and someone should supervise it in order for the best results to be obtained

Local applications of heat before passive or active exercise are valuable in limbering up the part or rendering it less painful Heat is too often used alone, and employed thus can give only temporary help The type of heat and the method of application depend upon the physician's choice While moist heat in the form of hot wet towels applied for a definite period, say twenty minutes, is inexpensive as well as foolproof, dry heat from any of the various infra-red lamps may also have definite usefulness The heat obtained by diathermy has distinct indications In applying moist heat, the patient should be warned against the use of electric heating pads, which may become wet and conduct the electric current through the body, with serious results

Creation of a Favorable Mental Attitude

A condition resembling melancholia is so commonly observed in persons suffering from toxic arthritis that the depth of the depression is often an indication of the patient's general condition, and must be actively treated It is important to point out to him the favorable developments in his condition, and to stress them in comparison with the unfavorable factors It is the encouragement which comes from realization of improvement that gives patients the courage to continue the program upon which ultimate recovery depends Success in developing this mental attitude depends on the physician's ability to apply psychological methods effectively

Relief of Pain

The treatment of toxic arthritis is too often limited to the relief of pain Most of the drugs advocated for the disease are intended primarily for that purpose If this were a self-limiting dis-

cises of gradually increasing difficulty for the various muscle groups should be given, always remembering that exercise of a muscle within its fatigue limit strengthens it, and exercise beyond that limit weakens it

The *skin* is of great importance as an excretory organ in chronic toxic conditions such as arthritis. This function, as well as its heat-regulating one, is invariably disturbed in toxic arthritis. The many small muscles controlling the hair follicles and the sweat glands require development, as well as the larger skeletal muscles. Protection of the skin against sudden and extreme drops in temperature is always necessary in the arthritic, but exposure to the air in a warm atmosphere with transient waves of moderate coolness does much to restore the skin function to normal. Bathing in water of slightly varying temperatures is less practical than bathing in air, and can be recommended only under exceptional conditions. A dry, glazed skin and constant perspiration are but different manifestations of a disturbed skin mechanism.

The *blood*, as in nearly all illnesses, suffers a decrease in the percentage of hemoglobin and in the number of red cells. The functioning of organs giving rise to the white cells is often impaired, but it is difficult to say when this is due to the disease and when to medicaments. When infection is present, the white-cell count is normally increased, as is the percentage of unsegmented polymorphonuclear cells, but because of the disturbed function of the organs giving rise to the white cells, in keeping with the subnormal functioning of the entire body, the cellular response may not follow normal lines. Ordinarily these organs recover without special treatment. Disturbances in the circulation have been studied at some length by Pemberton and his associates. They may be due to the lowering of the heart-muscle tone as well as that in the blood vessels themselves. A lowering of the blood pressure, both systolic and diastolic, would naturally be expected, especially in toxic arthritis of long standing, it returns to normal with increased body activity. It may be well at this point to speak of the importance of the skeletal muscles as accessory organs of circulation. The normal bending of the extremities at the joints, with compression of the veins between the muscles, helps to return blood to the heart. The inactivity of the extremities in arthritis hinders this return of blood, with resultant congestion.

Disturbances of the nervous system are frequently observed. It is not unusual to find the chronic arthritic emotionally unstable or even suffering from "nervous prostration." Psychoses, too, are not uncommon. These are manifestations of the subnormal condition of the nervous system in keeping

with the rest of the body, and they respond to measures used to restore the body as a whole to normal.

The *liver* is a most important organ in the treatment of toxic arthritis. Since it is the principal detoxicating organ, any disturbance of its function is bound to have a profound effect on the body's ability to recover from disease. Clinical tests for the determination of its function are not easily available or universally acceptable. It may be presumed that in arthritis the liver in its detoxicative function needs some assistance at intervals. Small doses of calomel followed by a saline cathartic have been found the most useful and dependable aid.

Protection of Joints

In toxic arthritis, which is a systemic disease with joint manifestations, the ultimate permanent joint damage is greatly influenced by the care of the joints during the activity of the disease. Even chronic toxic arthritis may be self-limiting, but recovery from the disease gives small satisfaction if the joint function is so greatly impaired that normal activity is difficult or impossible. *Rest* and *exercise* are the main methods of controlling the health of the joint structures, and heat is a subsidiary aid.

When rest is advisable, and when exercise, are difficult to state in general terms. Each case presents a problem all its own. In general, rest should be used when, owing to inflammatory reaction, any motion of the joint causes pain and muscle spasm. While it cannot be claimed that in rest there is no danger of inducing stiffness, it can be said without fear of contradiction that continued use of the irritated joint will result in changes which will eventually interfere with its motion. Rest during the active inflammatory period, on the other hand, by preventing further tissue irritation and by permitting the inflammatory reaction to reach its end point at the earliest possible time, allows motion to be started earlier and causes less damage to the joint structures.

There are several methods of obtaining rest, the careless application of which does not necessarily bring about the desired result. Rest in bed is presumably the most complete and effective form. Where the entire body requires rest this form is necessary, but not infrequently its attendant conditions make it impossible. In the first place, the bed must be conducive to rest. The author has observed situations in which a mattress which did not permit a change of position prevented the patient from sleeping for several days. The environment must be congenial and the bed must be neither too hot nor too cold. The inner spring mattress, so much in vogue at the present time and so widely advertised, is not free from serious

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

CASE 24161

PRESENTATION OF CASE

A forty-two-year-old, white, American factory worker entered the hospital with the complaint of hematuria and right-flank pain.

Six days before entry he began to pass grossly bloody urine. The following day he felt somewhat weak and faint and about noon began to have quite severe pain in his right flank which later extended around to the pubis. The pain was accompanied by a burning sensation on micturition and was only temporarily relieved by hypodermic injections. The hematuria and pain continued up to the time of entry, and he frequently passed clots of blood. He had had no previous genitourinary symptoms.

About twenty years before entry he had had a sore on his penis which was cauterized. For a period of two years following that he had had arm and hip injections. He denied ever having had gonorrhea. He had been married for twelve years, and his wife had never been pregnant. His past history and family history were otherwise negative. He had lost no weight and had always considered himself to be in the best of health.

Physical examination revealed a well-developed and nourished man apparently suffering considerable pain. The heart and lungs were negative. The blood pressure was 120 systolic, 80 diastolic. There were tenderness and spasm in the right upper quadrant and right flank, and the entire abdomen was held fairly tight. No masses were made out.

The temperature was 98.6°F., the pulse 100. The respirations were 22.

The urine was grossly bloody, had a specific gravity of 1.020 and contained a trace of albumin but no casts. The sediment of catheter urine specimens showed occasional granular casts and 300 red cells, 5 white cells and many bacteria per high-power field. The blood showed a red-cell count of 3,060,000 with 60 per cent hemoglobin, and a white-cell count of 9400 with 65 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 49 mg per cent on entry and 29 mg per cent two days later, the fasting blood sugar was 95 mg per cent, and the blood chlorides were equivalent to 103 cc of N/10 sodium chloride. The blood Hün-

ton test was positive, and the blood Wassermann negative. The icteric index was 8, and the van den Bergh was too low to read. A retrograde pyelogram showed abnormal soft-tissue shadows in the right psoas-muscle and right kidney areas. There were no areas of calcification, and the left kidney was not visualized. Injection of the right kidney pelvis and calices revealed intrinsic and extrinsic filling defects. There appeared to be a mass occupying the lower pole of the right kidney which displaced the pelvis upward, so that it was opposite the eleventh rib. The psoas muscle appeared to be obliterated by the mass. A film of the chest showed an unusually high, right diaphragm with a very much limited excursion. There was density in the right lower lobe, and the right costophrenic angle was obliterated. The heart and mediastinum were displaced to the right, and the right lung root was depressed. The aerated portion of the right lung was clear, and the left lung was negative. Three days later an intravenous pyelogram showed somewhat better visualization of the right kidney than previously. The minor calices on the right were slightly dilated, and the pelvis contained multiple irregular filling defects. The outline of the right kidney was clearly seen and appeared to be symmetrically enlarged, with the greatest enlargement in the region of the lower pole and medial aspect of the pelvis. The pelvis and ureter appeared to be displaced laterally. The lower portion of the psoas muscle was visible, but in its upper portion there was an increase in soft-tissue density, which obliterated the outline of the muscle and the kidney. The left kidney pelvis, calices and ureter appeared normal. An x-ray of the chest showed some improvement, with less marked density of the right lower lobe and slightly less elevation of the diaphragm. However, the diaphragm was still very high, and the heart and mediastinum were still displaced to the right of the spine. No fluid was demonstrated in the chest.

On the fourth day the white-cell count was 14,300 with 78 per cent polymorphonuclears, but the temperature remained normal. Two more urine examinations showed from 20 to 50 red cells per high-power field of the sediment.

On the sixth day an operation was performed.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON. I saw this patient three days after the onset of his illness, which occurred in another city, and think it should be stressed a little more that he was in a fair degree of shock. He was really ill with the onset of this hemorrhage. We did an intravenous pyelogram at that time, which showed no function of the right kidney and normal function of the left

ease of short duration, or if the patient tended naturally to recover, the use of pain-relieving drugs would not be objectionable, but under the actual conditions, the use of such medicines is open to serious question. If the measures enumerated under the first four objectives of treatment are effectively carried out, only a minimum of pain-relieving medicine will be required.

Of the many preparations offered for the relief of pain the one of sufficient strength to relieve the pain should be used. But the physician should know the action of the drug on the body as a whole, and should not utilize preparations which, while effective in relieving pain, do serious organic damage to the vital organs. In general, the salicylates and their well-known derivatives should be employed where mild remedies are called for. If it becomes necessary to use excessive quantities, this is evidence that they are not effective, and resort should be had to stronger preparations, even narcotics.

TRAUMATIC ARTHRITIS

Traumatic arthritis may be acute or chronic. The injury resulting from collision with a moving object is likely to be acute, while that resulting from the habitual use of the joint in a faulty manner is likely to be chronic. Acute trauma, unless it causes fracture of the bones entering into the joint, seldom reveals anything by x-ray. Chronic trauma invariably gives rise to hypertrophic changes in and around the joints. Whether the trauma be acute or chronic, rest of the affected joints effectively relieves the symptoms, although

one can hardly expect any modification of the hypertrophic changes of chronic irritation.

In the chronic form, the recognition of the causative agent, whether it be faulty posture, excessive abdominal girth or maldevelopment, is essential to the planning of adequate treatment. Control or correction of the traumatizing factors almost always ensures relief of pain and the halting of the arthritic process.

The surgical treatment of chronic arthritis is essentially the restoration of the joint so as to provide some measure of function after the arthritic process itself is no longer active. Surgical procedures during the active stage of the diseases are frowned upon by those who best understand the pathologic physiology of arthritic diseases.

SUMMARY

A new classification of arthritis based on recognizing bacteria, toxins and trauma as essential etiologic factors, is presented.

The treatment of arthritis is outlined. Bacterial arthritis is essentially a surgical disease, and the treatment is governed by surgical principles. The treatment of toxic arthritis represents the main problem of treatment in arthritis, and effective treatment involves removal of unfavorable factors, restoration of normal physiology, protection of the joints during treatment, creation of a favorable mental attitude, relief of pain. Traumatic arthritis is relieved by removing the traumatic factors.

158 Whitney Avenue

The patient had a small renal tumor — an adenocarcinoma — at the lower pole of the kidney. Curiously enough, there were not a great many vessels around the tumor, and I could see no bleeding point that I could definitely say was the origin of the perirenal hematoma. Although the patient was obese and had a lot of perirenal fat, the kidney freed up pretty well. The fat was quite indurated and I cleaned out the entire fossa and removed the kidney. There was no extension of the tumor into the renal vein or neighboring structures.

PREOPERATIVE DIAGNOSIS

Right kidney tumor with retroperitoneal hemorrhage

DR. ALLEN'S DIAGNOSIS

Tumor of the kidney with rupture of the capsule — probably hypernephroma

ANATOMICAL DIAGNOSES

Renal-cell adenocarcinoma.

Perirenal hematoma

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. The specimen showed a very sharply circumscribed carcinoma at the lower pole of the kidney, as Dr. Mintz described. We found one small eroded vessel in the capsule, not an impressive lesion to explain such massive hemorrhage, but I suppose it must have come from that spot.

DR. HAMPTON. The diffuse enlargement of the kidney is still unexplained because the kidney was not enlarged.

A PHYSICIAN. Both the hematoma and the tremendous amount of fat which extended anteriorly might account for the shadow.

DR. MALLORY. A great deal of the shadow must have been the hematoma.

DR. HAMPTON. That was our conclusion. Heretofore we have believed that if a patient had a ruptured kidney its outline would be obscured by the hemorrhage. We now have to change our point of view, and when we see a large kidney shadow in a case suspected of ruptured kidney, it may be of considerable significance.

A PHYSICIAN. Why were the heart and mediastinum displaced toward the diseased side?

DR. HAMPTON. He had massive collapse of the right lower lobe due to subphrenic irritation.

CASE 24162

PRESENTATION OF CASE

A thirty-four-year-old, white, American laborer entered the hospital with the complaint of right upper quadrant pain of seven months duration.

Seven months before entry he began to have daily attacks of dull, throbbing pain in the right

upper quadrant, just to the right of the umbilicus, which seemed to radiate down to the right iliac crest. The attacks lasted several hours, occurred more often at night, were unrelated to meals, defecation or activity, and were relieved by walking about but not by taking food or soda. The pain was severe enough to interfere with his sleep, but it did not keep him from working. Shortly after the onset his physician took x-rays of his stomach and gall bladder which were reported to be negative. He was put on a bland diet but this had little or no effect on his symptoms. The pain gradually increased in severity until two months before entry, when it became severe enough to force him to stop working. At about the same time he began to have eructations and flatus in increasing amounts. X-rays taken at that time were said to show "duodenitis," and he was put to bed for three weeks on a first-stage and then second-stage Sippy diet. The treatment had almost no effect on the symptoms, and he began to vomit occasionally, which he thought was due to the large amounts of cream. Five weeks before entry he was put back on a normal bland diet. Nausea and vomiting, however, continued once or twice a week and did give him slight relief from his pain. Three weeks before entry his previously regular bowel habits were interrupted, and he became constipated. His stools were lighter in color and his urine became dark. During the week before entry his pain became extremely severe and was occasionally sharp in character but never crampy. He had no definite jaundice, no hematemesis, no bloody or tarry stools and no cardiorespiratory or genitourinary symptoms. He lost 31 lb. in weight in the six weeks before entry. Sixteen years before entry he had had a nervous breakdown for which he was treated for six months with complete relief of symptoms. The past history was otherwise essentially negative, and the family history was not contributory.

Physical examination revealed a well-developed, slightly undernourished man in no acute distress. There was slight pallor of the skin and mucous membranes. The heart and lungs were negative. The blood pressure was 115 systolic, 75 diastolic. The abdomen was somewhat distended and tympanitic. The entire right side of the abdomen and the region over the sigmoid showed voluntary spasm and was tender to even light palpation. The tenderness was most marked just above and to the right of the umbilicus. The liver and spleen could not be felt, and no masses could be made out.

The temperature was 99°F., the pulse 100. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 3,500,000 with 55 per

All the other findings were about the same as those when he arrived here. I might also add that at that time his abdomen on the right side was rigid.

This retrograde pyelogram shows the displacement of the kidney pelvis upward and laterally as was described, with a large kidney outline—but larger at the lower pole—and with obliteration of the psoas muscle certainly in its upper half. The diaphragm on the right side was, as stated, high and relatively fixed. It is a fairly typical picture of collapse of the right lower lobe, with the fixation of the diaphragm and the general appearance that is usually seen in massive collapse. If he had a tumor of the right lower-lobe bronchus causing collapse of that lobe we should not expect fixation of the diaphragm. Then at examination three days later the lesion in his chest had definitely improved, as had the patient, an intravenous pyelogram done at that time showed function in a previously nonfunctioning kidney, but the filling defects were still present, both inside and outside the kidney pelvis. We thought the inner defects were probably blood clot and the lower defect very likely due to tumor, but we could not explain why the entire right kidney was enlarged and the psoas muscle obliterated, or why the diaphragm was high and fixed.

DIFFERENTIAL DIAGNOSIS

DR ARTHUR W ALLEN: What are the conditions that could cause hematuria? I suppose we must come down to that. We can fairly safely rule out a systemic disease, because blood was coming from only one kidney. In other words, we are probably dealing with a lesion in or around the right kidney.

A good deal of stress is laid on his probable early syphilis, twenty years before he came in. We have a positive Hinton and a negative Wassermann test. He had had two years of treatment which we assume to be antisyphilitic. Could this be a syphilitic lesion of the right kidney? The only thing that I should consider is the possibility of an aneurysm. It was probably not an aneurysm of the aorta, but I wonder if it could be one of the renal artery. I think the man is pretty young to have an aneurysm, even if he had had syphilis twenty years previously. However, we must keep that possibility in mind.

What neighboring structures could be involved that might cause this difficulty in the region of the right kidney? Could it be some outside influence such as disease of the liver or bowel, or could it be some trouble in the psoas muscle itself? We can rule out actual primary disease of the psoas muscle because the man had had an

acute onset only six days prior to entry. So far as I know, deep psoas abscesses or affairs of that sort must be of a chronic nature. This man had lost no weight. Also, I should be inclined to think that the obliteration of the psoas muscle as shown by x-ray was due to the acute episode and was secondary to whatever was the matter with the kidney. If we consider disease of the kidney, we think of the possibility of an aberrant vessel as a cause of hemorrhage and of the possibility of trauma, but we have no history of the latter. If he had had a serious blow in his loin just prior to the onset of his illness we should expect he would show a ruptured kidney with bleeding into the surrounding structures. Could any kind of infection in the kidney produce this picture? It rather seems as though that is not relevant because of the normal white count and temperature. The leukocytosis which developed four days later could be from the absorption of the hematoma which we assume was present about the kidney. Tuberculosis is another cause of kidney damage with blood loss, but this man was too well to have had tuberculosis of the kidney.

We therefore come down to a differential diagnosis of tumor of the kidney, such as hypernephroma or adenocarcinoma that has developed slowly without any effect on this man's general condition and has suddenly burst through its capsule. This sequence of events could explain the acute onset. It could explain the fixed diaphragm, the shadow over the psoas muscle and the hematuria. The only other thing that I can suggest is the possibility of aneurysm based on his old syphilis, and if it were an aneurysm it would have to be aneurysm of the renal vessel. I should expect that if it were aneurysm that there would not be so much obvious tumefaction of the kidney itself and that the kidney would be of normal size. The hematoma about it would, of course, explain the rest of the picture. I believe, however, that this is probably not an aneurysm but a tumor of the kidney, a hypernephroma that has spontaneously ruptured.

CLINICAL DISCUSSION

DR. E. ROSS MINTZ: The question of the type of incision to make was quite a problem. I finally decided to make a retroperitoneal incision, and when I came down to the lumbar dorsal fascia everything seemed to be all right. The moment I incised the fascia and put my hand around the kidney, out came a lot of blood clots. The clots were down in the fossa, and in freeing the kidney at the upper pole, I again ran into a tremendous amount of blood clot beneath the diaphragm. The diaphragm was evidently still pretty high.

adhesions arising from inflammation in neighboring organs, such as the gall bladder, from lesions of the pancreas, usually carcinoma, from enlarged neighboring lymph nodes, and finally there was one case described in which there was obstruction of the third portion of the duodenum from aneurysm of the abdominal aorta directly beneath it

The diagnosis is narrowed down to a tumor of some sort, which may be either extrinsic or intrinsic. Intrinsic tumors are either benign or malignant, and both are quite rare. The incidence of duodenal carcinoma is 0.03 per cent in a total series of 300,000 or 400,000 autopsies.

Of the malignant tumors, primary carcinoma of the duodenum is most frequent. Next in frequency is carcinoma of the papilla of Vater, next perhaps lymphosarcoma, of which there have been 15 cases reported out of a total series of 84 in the large and small bowels, then spindle-cell sarcomas, and most rarely, leiomyosarcoma of which only 2 were reported up to 1935. Extrinsic malignant tumors must be considered. They arise most commonly in the gall bladder or stomach, but frequently in the pancreas or any other neighboring organ. I do not know whether carcinoids should be classed as malignant tumors, Dr. Mallory could tell us more about that. These are the tumors which on staining show an affinity for silver and are found most commonly in the appendix, but have been reported in the small intestine.

The benign tumors are about half as frequent as the malignant ones. The commonest benign duodenal tumors are the adenomas, these are usually polypoid and arise from mucous cells or from Brunner's glands. The next in frequency are the fibromyomas, and finally a varied group including hemangioma, lymphangioma, neuroma, tumors arising from displaced pancreatic tissue, and so forth.

Most of the reports in the literature stress that all malignant and most benign tumors will bleed, so the presence or absence of bleeding does not help us much. I believe we can rule out carcinoma of the papilla of Vater because of the absence of jaundice. Of course any tumor of the duodenum may eventually cause jaundice by encroaching on the common bile duct, and it may be that the imperfect filling of the gall bladder was due to partial obstruction from the tumor mass. So far as I am concerned, the diagnosis of the nature of this tumor is reduced to a guess, and the only possible clue that I can see is the eosinophilia, which is something we often find associated with Hodgkin's disease or lymphosarcoma. As a pure guess I shall say that the tumor was a lymphoblastoma or lymphosarcoma of the duodenum.

PREOPERATIVE DIAGNOSIS

Cancer of duodenum

DR. LUDWIG'S DIAGNOSIS

Primary tumor of the duodenum (lymphoblastoma or lymphosarcoma?)

ANATOMICAL DIAGNOSIS

Carcinoma of duodenum

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. This patient was operated on by Dr. Arthur W. Allen, who found a large area of ulceration on the posterior wall of the third portion of the duodenum in approximately the region of the papilla of Vater. He felt from the gross examination that it was probably a tumor and that it had invaded the pancreas. He asked me to make a frozen section from a small piece of the ulcer margin, which he resected after opening the duodenum opposite the crater, but I was unable to find any tumor in it. However, he felt strongly enough that the lesion was malignant not to be unduly influenced by that and proceeded to do a cholecystgastrostomy because he felt certain that sooner or later it would obstruct the common bile duct, and also did a gastroenterostomy to relieve the duodenal obstruction. The later sections of the biopsy showed one minute fragment that was certainly carcinomatous and on the basis of that it was decided a couple of weeks later to make an effort at resection. This required removal of practically the whole duodenum and head of the pancreas, and the operation was made considerably harder by the fact that there was an anomalous insertion of the cystic duct. Normally the distance between the papilla and the point where the cystic duct joins the common bile duct is a matter of several centimeters so that ordinarily it would be possible to do such a resection without cutting the cystic duct. In this case, however, the cystic duct entered the common bile duct only 2 cm. from the papilla, right in the area of tumor involvement, so he was forced to anastomose the cystic duct to the common bile duct in the course of his operation, which prolonged it somewhat. The surgery was completed very successfully, but shock developed, and the patient died the following day. The surgical specimen showed an extensive carcinoma and I cannot say from the specimen whether it was primary in the duodenal wall near the papilla or actually in the papilla. My inclination is to believe that it probably started in the papilla but I think it ulcerated from the start and for that reason never obstructed the bile ducts. At autopsy it was found that there were metastases to one of the regional nodes, so that even if the patient had survived the resection he would not have lived a great many months.

cent hemoglobin, and a white-cell count of 13,600 with 75 per cent polymorphonuclears, 14 per cent lymphocytes, 2 per cent monocytes, 7 per cent eosinophils and 2 per cent basophils. The platelets were normal. The guaiac test on the stool was 3+. The blood Hinton test was negative, and a 1:40,000 tuberculin test negative.

A flat abdominal x-ray film showed several areas of calcification in the right side of the abdomen consistent with calcified mesenteric glands. There were no visible ureteral calculi, the kidneys were normal in size and shape, and there were no unusual soft-tissue masses. Two barium enemas showed no evidence of disease within the colon or terminal ileum. An x-ray of the chest was negative. A gastrointestinal series showed no evidence of lesions in the esophagus or stomach, and the duodenal cap was not deformed. At the junction of the second and third portions of the duodenum there was an upward convex curve with a questionable large area of ulceration in that region. No definite surrounding tumor mass was visible. Hourly follow-up films of the small intestine showed no evidence of disease. A re-examination four days later confirmed the presence of a lesion at the junction of the ascending and descending portions of the duodenum. There was a lobulated tumor mass, with probable ulceration, protruding into the lumen in that area. A Graham test showed very faint filling of the gall bladder, much less than in a normal individual.

The patient continued to have abdominal pain and during the first two weeks in the hospital lost 11 lb in weight. On the twenty-second day an exploratory laparotomy was performed.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES: The lower films simply show a negative colon and negative chest. In the upper group you can see this very definite deformity of the duodenum. The stomach appears normal. When you study these films more in detail the mucosal pattern is seen to be lost over a considerable area. There is an indentation of the duodenum, which is also somewhat dilated. The appearance in the duodenum is that of a large ulcerated mass. Here are the films of the gall-bladder region. There is a faint shadow of the gall bladder. There is no evidence of stones. It is normal in shape, and the only abnormality is the faintness of the shadow. A shadow like this sometimes occurs when the patient has been fasting before examination, I have seen it happen several times. Similar shadows are also seen in cases with tumor of the pancreas. Most of these cases have very faint or absent gall-bladder shadows. There is no reason to expect that the gall bladder is diseased. The lesion from our point of view should

be a tumor of the duodenum, and since I know the answer in this case I will not discuss the possibilities.

DR. ALFRED O. LUDWIG: I wonder if it is fair to ask whether by x-ray the lesion was intraduodenal. It was stated in the x-ray report that there was no visible tumor mass outside.

DR. HOLMES: Such a deformity of the duodenum as this I think would be more likely to occur if the lesion were in the duodenum, but one cannot say it did not extend into it from some external organ.

DIFFERENTIAL DIAGNOSIS

DR. LUDWIG: Before reading over this case my ignorance on the subject of tumors of the duodenum was almost complete, and the only way I could get anywhere was by studying the literature. So far as the story is concerned it is quite typical of tumor in the duodenum or tumor in the small bowel. Dull pain lasting several hours, of paroxysmal nature, is stressed many times in reports of these cases and is quite characteristic. It is quite interesting that mention is made in a number of these cases of early x-rays that have been said to show duodenitis. Nausea and vomiting, constipation and weight loss are also described as characteristic symptoms of tumors occurring in the duodenum or small bowel. Furthermore, the physical findings—the pallor and anemia, the distended abdomen, and the spasm and tenderness—are characteristic in cases that have tumors in this region. It is interesting that most of the cases described also stress the presence of a palpable mass. That may not have been felt here because it was too small or because of the spasm and rigidity that this patient had. The anemia is of a considerable degree,—3,500,000 red cells with 55 per cent hemoglobin,—and I think we can say that some of the anemia was certainly due to blood loss from the bowel. The patient had definite occult blood in the stools, although there was no history of any gross bleeding. I was also interested in the eosinophilia of 7 per cent, and it will eventually lead me to make a guess as to the diagnosis.

So far as the differential diagnosis of obstruction in the duodenum is concerned it has been divided according to its source into intraluminal, mural and extraluminal obstruction. The main causes of the intraluminal type are foreign bodies, particularly trichobezoars or hair balls. These are pretty well excluded by x-ray. Probably this case will fall into the mural group, and obstruction may occur from tumors in this region which are benign or malignant. Congenital stenosis of the duodenum also may cause obstruction, but again I believe that such a diagnosis is ruled out by the x-rays. Finally, there is the extraluminal cause of obstruction from congenital bands, from

be to study the needs of American medicine from the point of view of education, mobilizing the best current opinion regarding the different phases of professional training at its various levels, formulating standards adequate for those levels, and advising universities, hospitals, regulating bodies and governmental agencies on standards, methods and procedures. The end to be attained is better care of the sick. It is the improvement of the preparation of the physician for his peculiar function, from the days of his work as a premedical student until he retires from practice, that is the dominant idea of the new proposal.

There has been developing gradually in this country a widespread opinion that medicine, or speaking more generally the healing art, has been advancing in a too inco-ordinate fashion—a sequel to the remarkable progress in science and the growing general interest in health and ways of promoting it and ways of losing it. It impresses one as a jungle rather than as a well-ordered garden. There is little correlation, great independence of the parts, considerable overlapping and much waste. In fact we ought to have a planned economy, using the word economy in its remote rather than in its immediate sense.

If the plan means the use of intelligence by qualified individuals, the idea meets a favorable reception at once, provided that the authority granted to the body is persuasive rather than coercive. The proposed council would be only advisory in function, and one of the reasons why it has been suggested is fear of increased governmental interference with medical education and medical practice. There can be no doubt that the fear is justified and that there will be continued effort to increase the participation and therefore the control of the government in medicine. This may not be intrinsically wrong, but there are many thoughtful physicians whose opinion is expressed by the well-known saying "It is worse than a crime, it is stupid." Yet the mere mention of a national medical council arouses antagonisms and fears on the part of many persons, because too often "national" means "national gov-

ernmental" and we cannot get away from the idea of force or coercion.

There has developed through the past one hundred and fifty years a sense of the unity of these United States. It was one of the elements in the struggle which, according to our point of view, we call the War of the Rebellion or the Civil War or the War between the States. In the World War it was intensified. It grows with the advance in methods of communication and of transportation. In time and space the widely separated North and South and East and West are closer together now than ever before. There has occurred with this development an extension of the intrusion of the national government into many fields. A critical question is, How far shall it intrude? What is a just and wise delimitation of the field for the national government? No one can say offhand, but there is no human intelligence capable of directing our lives wisely from Washington or from any other place on earth.

It is the fundamental democratic dogma that the adult individual is the best guardian of his own rights and the best director of his own life. No matter what qualifications are necessary because of collectivism or socialism or communism, using these words in their general sense and not in their perverted and more frequent acceptation, individualism will endure. It is the infinite worth of the individual that these last 1900 years have been trying to impress upon us. Lord Acton said of liberty "It is the delicate fruit of a mature civilization." Is there liberty in Socialism or Communism or Nationalism? This is an acid test, devastating if applied to most contemporary organized movements and activities.

A truly national medical council, carried on under the idea that better ways can be found for solving the health problems of the nation and that, in general, people will do what is best for themselves if they know what is best, such a medical council, using science and intelligence and moral suasion rather than coercion, whether direct or indirect, might make a great and significant contribution to our national life. We need to learn

FOR VALOR

THE six members of the Governor's Council, the majority of members of the Massachusetts Medical Society, the members of many other organizations, and the numerous individuals, all interested in the health of the people, deserve well of the Commonwealth of Massachusetts. By their actions or efforts, an attempt to lower the standard of public-health administration in this Commonwealth has been overthrown, and because of this, we herewith offer this citation.

The fact that we have been given this exceptional privilege should make everybody, but especially every doctor, stop and think. Experienced practical politicians will generally admit, when speaking off the record, that when it is organized, the potential vote-getting power of the medical profession is the greatest that exists in any po-

litical unit. Its unpredictability, however, is as great as its potential strength. It can be counted on to enforce any measure that is for the ultimate good of its patients, and therefore of the poor and underprivileged. But, because of its uncompromising intellectual honesty, it has the habit of making up its own mind about what the actual rather than the political worth of the proposition in question may be. This is very confusing to the *died* in-the-wool politician who regards such a matter as the public health of the State as of little relative importance compared to party regularity or the "affection of the people" of any community.

Let us not forget this illuminating experience and let us not fail to remind those courageous men who, by their vote, put public welfare above private political expediency that we, as individuals, are grateful so grateful, that when they again have to speak up for the poor, the sick, the crippled and the dying,—as we have been warned they will,—they can count on our wholehearted backing.

A NATIONAL MEDICAL COUNCIL

News from the recent meeting in Chicago of the Council on Medical Education and Hospitals of the American Medical Association suggests a somewhat new approach toward the solution of the problems confronting the medical profession. It is perhaps primarily a shift in emphasis, and the dominant note struck is "education." References to the address of Dr. Willard C. Rappleye have been made in the lay press, but what has attracted most attention is the suggestion that there be formed a National Medical Council, to be composed of representatives of universities, medical schools, hospitals, the practicing profession, specialist examining boards, state licensing boards and public-health agencies. It is interesting to note that this proposal was made during a discussion at the Congress on Medical Education and Licensure, with representatives of the hospitals participating.

The functions of the proposed council would

little success—in the ice-cold streams of New England during early spring

His death was a great shock to his friends, who were legion. He certainly made the most out of life, and to many of us there must creep in the hope that we may, within our spans, be able to accomplish as much as he did

CASE HISTORY No. 68 CENTRAL PLACENTA PREVIA

Mrs. E. K., a thirty-five-year-old multipara in her thirty-sixth week of pregnancy, was referred by her local physician to the prenatal clinic on February 14 because of bleeding.

There was no record of the family history. Her past history was noncontributory except for influenza in 1918. She had had five normal deliveries and one forceps delivery of a stillborn baby, which was said to have been very large. Catamenia began at fourteen, had a twenty-eight-day cycle and lasted five days without pain. Her last period was June 15, making the estimated date of delivery March 21.

Upon physical examination the lungs showed no rales and were resonant throughout. The heart showed no enlargement, there were no murmurs. The blood pressure was 120 systolic, 70 diastolic. The fundus was 27 cm. above the symphysis, and the baby was in LOA position. The urine showed no albumin or sugar.

The present pregnancy had been normal until January 25, when the patient, while trying to vomit, had passed about a pint of blood by vagina. She passed a large clot following this but had no further flow. On February 6 the patient awoke during the night to find that she had had a small amount of bleeding. Since that time she had been in bed and under her physician's care. During the night of February 11 she awoke to find herself in a pool of blood, and bleeding of an undetermined amount continued for about four hours. At that time the patient passed a large clot, and the bleeding stopped. She stayed in bed from that time until her admission to the hospital and had no further complaints except marked thirst. All these spells of bleeding were painless, and there was no evidence of uterine

cramps or spasm. There was no abdominal tenderness at any time.

On arrival at the hospital the patient was sent at once to the labor room and a delivery room was set up with a bagging set. Her blood was typed for transfusion. The patient was prepared in the usual manner and examined by the attending physician and the resident. The cervix was patulous and admitted two fingers without difficulty. The placenta could be plainly felt, and on gentle exploration appeared to extend about the whole circumference of the cervix.

As the resident withdrew his fingers, they were followed by a stream of bright blood. A No. 6 bag had already been tested, folded and clamped by uterine forceps. The bag was at once inserted into the cervix and filled with fluid, thereby controlling the hemorrhage.

The patient started shortly in regular labor, and in about two hours the cervix was fully dilated. During labor the blood pressure varied between 100 and 115 systolic, and the pulse rate averaged 92. As soon as the bag was through the cervix, it was removed from the vagina and the baby delivered by internal podalic version. The placenta and membranes came away at once. The baby breathed spontaneously and weighed 6 lb.

On examination the placenta showed a central area covered with dark blood clot.

After delivery the uterus behaved well, and there was no unusual bleeding. The patient was given posterior pituitary extract and ergot, one ampule of each. Ergot by mouth, to maintain firm contraction, was commenced as soon as the patient could retain it. Recovery was uneventful, and mother and baby were discharged well.

Comment. Although painless vaginal bleeding in considerable amount during the last third of pregnancy is always suggestive of placenta previa, positive diagnosis can be made only by inserting the finger through the cervix and feeling the placenta. As in every case where immediate delivery may be necessary, all surgical precautions in the preparation of patient and doctor must be taken.

This case well illustrates what additional preparations are necessary to insure the minimum risk for the mother and baby. If the family physician had tried to diagnose the condition at home, the patient might have died from hemorrhage before reaching the hospital. The patient should have been hospitalized on January 25, when bleeding first occurred. The favorable outcome in this case is no argument for procrastination. It is not safe to allow a patient to bleed two or three times without an attempt's being made to determine the source of the bleeding.

Simply to put a patient to bed who bleeds in the

to distinguish between our nation and our government, and to realize how much there is which we do as a nation in which the federal government has properly no part

A penetrating critic of modern life has said "The dangers arising are great, particularly in our democratic societies. The directive force of reason is weakened. The leading intellects lack balance. They see this set of circumstances, or that set, but not both sets together. The task of co-ordination is left to those who lack either force or the character to succeed in some definite career." The pertinence of this to governmental direction is perhaps apparent. The problem is, first, to secure, for such co-ordination as is desirable, persons who for sheer ability have succeeded in some definite career, and secondly, to refuse to grant them coercive power, so that they may persuade rather than compel.

OBITUARY

BENJAMIN WHITE

1879-1938

BENJAMIN WHITE was born in Cooperstown, New York, on January 15, 1879. He received a Ph B degree from Yale University in 1900 and was appointed Robinson Fellow in the same year. While holding this fellowship he studied in Berlin, Munich, Vienna and London, and in 1903 was given a Ph D degree by Yale. During the same year he was made assistant director of the Department of Bacteriology, Hoagland Laboratory, Brooklyn, New York, and in 1907 was appointed director. Because of ill-health he was obliged to go to Saranac, New York, in 1909, and after recovering from his acute illness, worked as an assistant in the Saranac Lake Laboratory until 1911, when he returned to his former position. He also served as consulting bacteriologist to the Long Island College Hospital from 1911 until 1914, when he was appointed assistant director of the Bacteriological Laboratories, New York City Department of Health, and was placed in charge of the biological laboratories at Otisville, New York. In 1920 he was made director of the Division of Biological Laboratories, Massachusetts Department of Public Health, with his chief duty the supervision of the Antitoxin and Vaccine Laboratory at Forest Hills. This position he held until 1933, when he was forced to resign because of ill-health.

For the past few years he had lived in New York City, spending most of his time collecting data for and writing a book, *The Biology of Pneumococcus*, which was published this year by the Commonwealth Fund. At the time of his death he was retained by the Commonwealth Fund in a consulting capacity.

When he came to Boston in 1920 he was made a member of the Department of Preventive Medicine and Hygiene, Harvard Medical School, and at the time of his retirement was assistant professor in this department and also in the Department of Bacteriology. In 1920 he was appointed lecturer on biologic assaying and immunology at the Massachusetts College of Pharmacy, and became an associate professor in 1922, which position he held until 1925. Since 1926 he had been a member of the editorial board of the *New England Journal of Medicine*, and during the War had served as a captain in the Sanitary Corps.

He was a fellow of the American Academy of Arts and Sciences, an honorary fellow of the Massachusetts Medical Society and an honorary member of the Aesculapian Club. His memberships included the National Tuberculosis Association, the American Association of Pathologists and Bacteriologists, the Society of American Bacteriologists, the American Public Health Association, the Society of Experimental Biology and Medicine and the American Association of Immunologists.

In 1935 he married Nona Solari, of New York City, and those who knew him intimately realize that the last three years of his life were his happiest. Severely handicapped by a badly damaged heart, he was able to carry on, even spending several months abroad during the past summer, and as a climax, he completed his book and so handed down to posterity a knowledge of intricate facts possessed by few and never before made available to others.

He was an indefatigable worker, and his insistence for detail and accuracy was largely responsible for the many improvements in the manufacture, distribution and use of biological products that had their origin in the Antitoxin and Vaccine Laboratory while he was director. The laboratory itself was a model institution, and the people of Massachusetts received the benefits derived from the distribution and use of biological products of the highest grade.

A great lover of the out-of-doors but necessarily limited in activity on account of health, his favorite avocation was trout fishing. Educated on the Beaverkill and the Esopus, he was an expert with the dry fly, and refused to degrade himself with the lowly worm even when fishing—usually with

last months of her pregnancy is unintelligent procrastination. An examination is imperative, and a hospital is the only place where such examination can be intelligently made. It was really good fortune that serious hemorrhage did not occur before this patient reached the hospital. The method of treatment after the patient reached the hospital was ideal.

The baby's risk depends on how extensively the fetal circulation has been damaged by the placental separation, which, in turn, is conditioned, to a large extent, by the site of placental implantation, the method of delivery is of secondary importance.

LEGISLATIVE NOTES

On April 1 the Committee on State and National Legislation issued a new Legislative Bulletin which will be sent to any fellow on request.

Since April 1 the following changes in status have taken place in the bills in which we are interested.

House Bill 39, relative to the definition of the terms 'rendering medical service,' 'practice of medicine' and 'holding one's self out as a practitioner of medicine' and its companion bill House Bill 40, exempting certain classes, such as dentists, optometrists and so forth, from the above bill, have been voted 'no legislation necessary' by the Legislature.

House Bill 1529, which provided for the furnishing by the Commonwealth of free oxygen tents to the hospitals in cities of over 30,000 population, has been given 'leave to withdraw' by the Legislature, as has House Bill 1650 which was an act changing the charter of Middlesex University.

House Bill 758, which was a bill to postpone the operation of the statute raising the standards of medical education from January 1, 1939, to January 1, 1942, has been redrafted and is now to be known as House Bill 1845. The new bill postpones the action for two years instead of three years and has been passed in the House.

House Bill 456, which provided for a state fund to replace the present workman's compensation law, has been given 'leave to withdraw' by the Legislature.

House Bill 1084, which provided that the restrictions in regard to graduates of a poorer grade of medical schools should be lowered, has been given 'leave to withdraw,' and this action has been approved by the Senate.

Of House Bill 1279 and Senate Bill 361, both of which provided for the issuance of certificates of approval for bacteriological laboratories, the former has been referred to the next annual session and the latter given 'leave to withdraw' by the House. Final action by the Senate, however, has not been taken.

The bill for the annual registration of physicians, House Bill 41, has been voted 'no legislation necessary' by the House. It will now go to the Senate.

House Bill 42, relative to the suspension or revocation of certificates to practice medicine, has been passed to be engrossed. We favored this bill.

Of the fifty six bills in which the Committee on State and National Legislation is interested, which were before the current Legislature, thirty-one have been disposed of for this session.

MEDICAL POSTGRADUATE
EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 25

BARNSTABLE

Sunday, May 1, at 4:00 p. m., at the Cape Cod Hospital, Hyannis. Subject The Use and Misuse of Prontylin. Instructor R. Cannon Eley. John I. B. Vail, *Chairman*

BERKSHIRE

Thursday, April 28, at 4:30 p. m., at the House of Mercy Hospital, Pittsfield. Subject The Use and Misuse of Prontylin. Instructor Benjamin W. Carey, Jr. Melvin H. Walker, Jr., *Chairman*

BRISTOL SOUTH (Fall River Section)

Monday, April 25, at 4:30 p. m., at the Union Hospital, Fall River. Subject Toxemias of Pregnancy. Instructor Joseph W. O'Connor. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*

ESSEX NORTH

Friday, April 29, at 4:30 p. m., at the Lawrence General Hospital, Lawrence. Subject Toxemias of Pregnancy. Instructor James C. Janney. John Parr, *Chairman*

FRANKLIN

Wednesday, April 27, at 8:00 p. m., at the Franklin County Hospital, Greenfield. Subject Early Syphilis. Instructor Francis M. Thurmon. Halbert G. Stetson, *Chairman*

HAMPSHIRE

Thursday, April 28, at 4:00 p. m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p. m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject The Use and Misuse of Prontylin. Instructor R. Cannon Eley. George D. Henderson and George L. Schadt, *Chairmen*

STILLMAN, JAMES S., 164 Elgin Street, Newton Centre.
Harvard Medical School, 1934

TAURO, ARTHUR L., 53 Fellsway West, Medford
Boston University School of Medicine, 1936

WALSH, JAMES R., 189 Concord Street, Framingham
University of Pittsburgh School of Medicine, 1928

WHITE, SEYMOUR J., 17 Washington Street, Malden
University of Paris Medical School, 1936

Submitted by Alexander A. Levi, *Secretary*

NORFOLK DISTRICT

AISNER, MARK, 36 Fessenden Street, Mattapan
Tufts College Medical School, 1935

BALABAN, JOSEPH S., 392 Broadway, South Boston (Residence Brookline.)
University of Constantinople, 1919

BETTS, REEVE H., 1101 Beacon Street, Brookline
Harvard Medical School, 1933

BIGELOW, ROBERT B., 302 Adams Street, Milton
University of Michigan Medical School, 1932

BIGURIA, FERNANDO, 214 Riverway, Roxbury
National University, Guatemala City, C A, 1929

CARNICELLI, THOMAS J., Exchange Street, Millis
Tufts College Medical School, 1934

CHRISTIAN, HENRY A., 1731 Beacon Street, Brookline.

Middlesex College of Medicine and Surgery, 1932.

before consulting a physician, but it is far better than the figure of more than six months. The physicians of Massachusetts are taking the lead in referring patients to the cancer clinics. In the early days of the movement, many patients came to the clinics because of newspaper publicity. The percentage referred by physicians was relatively small. Today, this has entirely changed. Nearly 90 per cent of all cancer patients who are attending the Massachusetts cancer clinics are referred by their physicians. The teaching clinics have had a great deal to do with this change in the referring of patients by physicians. Will you explain the development of these clinics?

Dr Chadwick Teaching clinics were instituted in 1933. They are conducted in the same locality and at the same time as one of the regular clinics. The local medical profession invites to these special clinics some individual physician, whose specialty is cancer, he meets with the local group and discusses from his experience improved means of diagnostic procedure and treatment. The number of such clinics has increased from 2 in 1933 to 69 in 1937. In the first year, only 75 physicians attended these clinics. In 1937, 1384 physicians were in attendance. This enormous increase is another index of the success of the Cancer Program. Has there been an increase in the number of individuals with cancer coming to the clinics?

Dr Lombard The total individuals with cancer attending the clinics has steadily increased. In the first year there were 302. In 1937 there were 1319. The total attendance at the cancer clinics in 1937, including new and old cancer patients, as well as non-cancer patients, was 12,454. Of the new patients, about one third had cancer. Of the old patients, a much larger percentage had cancer. Of the group of 302 cancer patients who came in 1927, 24 per cent are alive today.

Each part of the cancer program that has been discussed so far has depended for its success on the mutual efforts of the medical profession, the public health profession, and the laity. Of all the underlying parts of the program, which do you consider the most completely dependent on the individual co-operation of every person in the Commonwealth and the most far-reaching in end result?

Dr Chadwick Without any hesitation, I feel that our state-wide educational plan, which we call advisedly the Co-operative Cancer Control Committee Program, is the cornerstone of the Massachusetts Cancer Program. This program for the dissemination of information concerning cancer consists in the teaching of exact knowledge by an authority in the person of the family physician to the individual as one of a small group. To accomplish this in a state of 355 communities with a population of nearly 4,500,000 and nearly 7000 physicians, each community in the State has, or is in the process of having, a Co-operative Cancer Control Committee. The individual committees are integral parts of the state-wide Co-operative Cancer Control Program. Two hundred and seventy-five of the communities in the state are organized at the present time. These committees differ from many other educational committees in that they are not selective and consequently restricted to limited groups or classes but are rather inclusive in nature and represent every type of group and individual in the community. Over 6000 representatives have agreed to serve on these committees and to urge their respective clubs or groups to have annual talks on cancer given by local physicians. The records show that over 100,000 individuals in this State were reached with cancer talks during 1937.

Dr Lombard This educational program, which began in Massachusetts and is being watched with interest all over the world, seems to be direct and simple in plan. Why do you think it has been so much more successful than other educational plans for the control of this disease?

Dr Chadwick The essence of the success of the educational methods of the Massachusetts Cancer Program lies in its inherent sharing of known facts about cancer by a generous and informed profession with a co-operative and receptive public. Fears are not stressed; they are rationalized. Symptoms are not presented as the basis of exact knowledge; they are merely alluded to in the sane discussion of the larger problem. The physician, with his increasing interest in the progressive steps in the knowledge of cancer, the disease, presents the subject simply and intelligibly. The public, responding as an individual would respond to a real discussion of an absorbingly interesting subject, rises to the mental challenge of this approach. As a result, all classes, groups, races and professions are united in this basic co-operative and successful program which disseminates exact knowledge concerning cancer. This engenders a realization of the need for prompt action. Exact knowledge and prompt action effect control.

RECENT DEATHS

BULLIAN—MOSES BULLIAN, M.D., of 274 Seaver Street, Roxbury, died November 17, 1937. He was in his fifty-third year.

A native of Russia, he received his degree from Kiev Medical Institute in 1912. He was a fellow of the American Medical Association and the Massachusetts Medical Society.

His widow survives him.

COTTON—FREDERIC JAY COTTON, M.D., of 239 Beacon Street, Boston, died April 14. He was in his sixty-ninth year.

Born in Prescott, Wisconsin, he was graduated from Harvard University in 1890 and received his degree from Harvard Medical School in 1894. Following his graduation he was for several years house surgeon at the Massachusetts General Hospital, after which he studied at the University of Vienna. He also attended the College of Physicians and Surgeons in New York City. For several years Dr. Cotton was assistant surgeon at the Children's Hospital, following which he became head of the bone and joint department of the Boston City Hospital, a post which he held from 1902 to 1931. He was chief-of-service at the Boston City Hospital from 1920 to 1931, and in 1927 organized the Bone and Joint Service. Upon resigning in 1931 he was elected president of the hospital staff. At this time he was also assistant professor of surgery at Tufts College Medical School and a lecturer on bone and joint surgery at Harvard Medical School and Harvard Medical School, Courses for Graduates.

Dr. Cotton was a founder and member of the board of governors of the American College of Surgeons. His affiliations included fellowships in the American Surgical Association, the American College of Surgeons, the Massachusetts Medical Society and the American Medical Association, and memberships in the Boston Surgical Society, the Boston Orthopedic Club and the New England Surgical Society. He was an honorary member of the American Academy of Orthopedic Surgeons.

His widow and a daughter survive him.

HAMPSHIRE

Wednesday, April 27, at 4 15 p m, in the Nurses Home, Cooley Dickinson Hospital, Northampton. Subject Some Complications of Labor Analgesics in Labor Instructor James C Janney Warren P Cordes, *Chairman*

MIDDLESEX SOUTH

Wednesday, April 27, at 4 00 p m, at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject Drug Therapy in Pediatrics Instructor Warren R. Sisson Edmund H Robbins, *Chairman*

THE MASSACHUSETTS CANCER PROGRAM

Dr Chadwick A year has passed since I have had an opportunity to discuss the Massachusetts Cancer Program with you. At that time a report of the accomplishments of the first ten years was presented. Tonight the achievements of another year will be demonstrated. And yet, these remarkable incidents can scarcely be called the results of any single year. A program that is so thoroughly integrated among all the individuals in the State gains momentum as it progresses, and each year represents the cumulation of all preceding years rather than the limited results of the single year in question. This month is Cancer Month' throughout the United States. Massachusetts is co-operating by making public the regular activities of the State Cancer Program, for this State has twelve cancer months. For example, during this month of April there will be, in 21 strategic points throughout the State, 76 state aided cancer clinics at which there will be an average attendance of 20 physicians and an average attendance of 18 patients. At each of these 21 cities, in place of one of the regular clinics, will be a cured-cancer clinic at which cured cancer patients have volunteered to present themselves to show what has been done for them and what may be done for others. On April 1, for example, 18 cured cases were presented at the Springfield clinic, 10 were presented at the Greenfield clinic, and yesterday 30 were presented at Fitchburg and 5 at Newburyport. More than 300 cured cases will be presented altogether throughout the State. The other clinic communities in which cured cases will be shown are Boston,—at the Beth Israel Hospital and the Boston Dispensary,—Brockton, Fall River, Gardner, Gloucester, Hyannis, Lawrence, Lowell, Lynn, New Bedford, North Adams, Northampton, Pittsfield, Worcester, Pondville and Westfield. There is hardly a residence in the State more than twenty five miles distance from one of these centers. This new presentation of these 21 cured-cancer clinics in these points near every home will bring the fact of the curability of cancer close to every person. Many of us recognize that most cancer is curable if treated early, but to see individuals who have had the disease and now are free from it and have had no sign of a recurrence for at least five years, is a comforting and reassuring sight.

Dr Lombard Before you mention the other parts of the regular program that are being publicized this month, will you explain what constitutes cured cancer in the eyes of physicians conducting these clinics, and the number of cases that may be justifiably considered to be cured cancer cases?

Dr Chadwick A physician speaks of a cured cancer case as any individual who once had the disease and has

been free from it for at least five years. This period of time is chosen because if there is going to be a recurrence of the disease, it usually occurs within this interval. Therefore, the only cures obtained at our cancer clinics that can be considered are those that came between 1927 and 1933. More than 1000 individuals are included in this group. This group of cured cases from our clinics does not begin to measure all the cured cancers that have occurred within this same period, as only a small percent age of the individuals with cancer go to the Massachusetts Cancer Clinics. It is a conservative estimate that approximately 1000 individuals are being cured annually in this State. Will you tell of the call that came to your office recently concerning a cured cancer?

Dr Lombard That call was a very interesting one, and is, in a way, symbolic of what is possible in this State. The woman who phoned said she was aware of the work that the State was doing and wanted to help. She said her mother had been cured of a cancer fourteen years before and was now ninety years old, and was well and active. All the records of the case had been collected by these two public spirited women, including the original pathological slide with its cancer tissue. The woman who had been cured volunteered to appear at any of the cured-cancer clinics or to help in any way she could to publicize the curability of cancer. This demonstrates again the basic trait of the people of our Commonwealth—a sense of community responsibility, a willingness to work, without reward or recognition, for the common good. What other activities are going on in connection with the Cancer Program this month?

Dr Chadwick The tumor diagnostic service will receive specimens suspected of being cancerous from approximately 275 physicians. These specimens will be examined immediately upon their receipt and a detailed report will be despatched without delay to the physician who sent the specimen. This is a service that is conducted at no cost to physician or patient. The Pondville Hospital has 140 beds for the care of patients with cancer. The Westfield State Sanatorium has a 50-bed capacity for the care of cancer patients. The statistical or research section of the cancer division will continue its several studies on the various aspects of the disease. The *New England Journal of Medicine* will publish an important contribution to the literature from this department on the "Hereditary Aspects of Cancer," based on years of research. Two hundred and seventy five of the 355 communities in Massachusetts, which have already been enrolled in the Co-operative Cancer Control Committee Program, will hold more than 1000 group meetings attended by nearly 50,000 persons, and addressed by more than 1000 local physicians. This, in brief, is the program of "Cancer Month in Massachusetts—a State of nearly 4,500,000 inhabitants, nearly 7000 physicians, and 355 communities. Are there any measures to show just how effective this State Cancer Program really is?

Dr Lombard The most effective measure of the significance of the Massachusetts Cancer Program is the concrete evidence that more individuals are going to their physicians as soon as they notice an abnormality. The percentage of individuals who sought the advice of their physicians within the first month of the disease has increased from 12 per cent in 1933 to 18 per cent in 1937. The average delay of all patients has decreased from more than six months in the first nine years of the program to five months in 1936 and 1937. To be sure, five months is a long period for an individual with cancer to delay

Association.

*Ladd's Lads**Manchester String Ensemble*BOARD OF REGISTRATION
IN MEDICINE

Twenty candidates presented themselves at the meeting of the Board held on March 10. Eight candidates were permitted to take the written examination in which all were successful.

The annual directory of physicians licensed to practice in the State has been published. Copies may be obtained from Miss Harriet Parkhurst, State House, Concord, or from the secretary, Dr. Fred E. Clow, Brown House, Wolfeboro. The Board requests that physicians consult this list with a view to preventing practice by unlicensed persons. Recently a physician from a nearby state has maintained an office from which he has treated many patients, wholly without permission or legal authority. Infractions of the Medical Practice Act will be promptly reported to the county solicitors, once they are called to the attention of the Board or its investigator.

COMMITTEE ON CONTROL OF CANCER

The following letter has been mailed to all physicians in the state:

During and following the educational campaign of the Women's Field Army, you may be consulted by patients asking you to decide whether they have cancer. In order to assist you in such an examination, the following suggestive guide has been formulated:

1. Examine lips, buccal and pharyngeal membranes for ulcerations or nodules, and the cervical lymphatic areas for nodular enlargement.
2. Any patient with unexplained hoarseness, of over one week's duration, should be examined by an expert laryngologist.

3. Examine skin for new growths, bleeding ulcerations or scaly dry crusts. Black moles need special consideration and expert advice.
4. Examine female breasts (and occasionally male) for lumps and for serous or bloody discharge from nipple.
5. Inquire minutely into symptoms of digestive disturbances, and if you cannot relieve them in a very short time, advise x-ray examination.
6. Examine carefully any patient with fairly rapidly increasing constipation, including digital rectal examination, stool examination for occult blood, and if indicated, an x-ray barium enema.
7. Rectal bleeding demands, first, digital examination, if no diagnosis can be made, then examine by proctoscopy. If no cause for bleeding is found with these two methods, then an x-ray barium enema should be advised. A barium enema should never be given until the rectum has at least been examined digitally.
8. Bimanual pelvic examination should be made in all women as a routine procedure. Note mobility, size and shape of uterus, appearance of cervix with especial attention to erosions. Note enlargement or tenderness of adnexa. If there is a history of abnormal bleeding, not definitely accounted for by the above examination, advise a diagnostic curettage.
9. If the patient has had urinary bleeding, advise immediate cystoscopy.
10. General examination should include the chest (if there is cough), abdominal palpation, and the examination of subcutaneous tissues and bones for possible tumors.

If the above rules are adhered to in making a physical examination, it is certain that fewer early cancers will be overlooked. Always remember that the fate of the cancer patient rests with the physician first consulted.

DISTRICT SOCIETY NEWS

Officers of the Belknap County Medical Society for 1938 are Dr. Harry Cbeney, president, Dr. M. Alice Normandin, vice president, and Dr. Clifford S. Abbott, secretary-treasurer. The next meeting will be held on April 12, with Dr. J. Russell Perley in charge of the program.

NOTES

Dr. George R. Eades, school physician, gave a lecture at a Parent-Teachers Association meeting at Keene on "Keeping the Child Well. Value of health clinics."

The quarterly meeting of the New Hampshire Graduate Nurses Association was held at the Elliot Community Hospital, Keene, under the presidency of Miss Ruth Whitcomb, of Concord, on March 15. The principal address was given by Mrs. Evangeline Morris, of the Simmons College faculty. Miss Marion Northway, of Milton and Mrs. Melanie Proulx, of Manchester, were nominated for membership on the State Board of Nurse Examiners. Sectional meetings of public health nurses, private-duty nurses and the League of Nursing Education were held in the morning. It was voted that the annual meeting be held in Manchester next June.

FISKE — EUSTACE L FISKE, M.D., of 807 E. Windsor Road, Glendale, California, died March 20. He was in his seventy ninth year.

Dr Fiske was graduated from Harvard Medical School in 1886. He was a fellow of the American Medical Association and the Massachusetts Medical Society.

PIKE — FORREST W PIKE, M.D., of Stoneham, died December 31, 1937. He was in his eightieth year.

He was a native of Stoneham and received his early education there. After receiving his degree from the University of Vermont College of Medicine, he served his internship in Poughkeepsie, New York, beginning private practice in North Chelmsford before finally settling in Portsmouth, New Hampshire. He practiced there for over thirty years, retiring twelve years ago.

Dr Pike was a fellow of the Massachusetts Medical Society and a member of the American Medical Association. He was a member of the Masonic Order.

Four nieces and two nephews survive him.
